device_width Fields

Bit	Name	Description	Access	Reset
1:0	value	Controller will read Electronic Signature of devices and populate this field. Software could also choose to override the populated value although only one value is supported. The values in this field should be as follows[list][*]2'h00 - 8bit device[*]All other values - Reserved[/list]	RW	0x3

device_main_area_size

Page main area size of device in bytes

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80170

Offset: 0x170

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x0															

device_main_area_size Fields

Bit	Name	Description	Access	Reset
15:0	value	Controller will read Electronic Signature of devices and populate this field. The PAGE512 field of the System Manager NANDGRP_BOOTSTRAP register will determine the value of this field to be 512. Software could also choose to override the populated value.	RW	0x0

device_spare_area_size

Page spare area size of device in bytes

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80180

Offset: 0x180

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value															
RW 0x0															

device_spare_area_size Fields

Bit	Name	Description	Access	Reset
15:0	value	Controller will read Electronic Signature of devices and populate this field. The PAGE512 field of the System Manager NANDGRP_BOOTSTRAP register will determine the value of this field to be 16. Software could also choose to override the populated value.	RW	0x0

two_row_addr_cycles

Attached device has only 2 ROW address cycles

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80190

Offset: 0x190

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag
															RW 0x0

two_row_addr_cycles Fields

Bit	Name	Description	Access	Reset
0	flag	This flag must be set for devices which allow for 2 ROW address cycles instead of the usual 3. Alternatively, the TWOROWADDR field of the System Manager NANDGRP_BOOTSTRAP register when asserted will set this flag.	RW	0x0

multiplane_addr_restrict

Address restriction for multiplane commands

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801A0

Offset: 0x1A0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag
															RW 0x0

multiplane_addr_restrict Fields

Bit	Name	Description	Access	Reset
0	flag	This flag must be set for devices which require that during multiplane operations all but the address for the last plane should have their address cycles tied low. The last plane address cycles has proper values. This ensures multiplane address restrictions in the device.	RW	0x0

ecc_correction

Correction capability required

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801B0

Offset: 0x1B0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								value RW 0x8							

ecc_correction Fields

Bit	Name	Description	Access	Reset
7:0	value	The required correction capability can be a number less than the configured error correction capability. A smaller correction capability will lead to lesser number of ECC check-bits being written per ECC sector.	RW	0x8

read_mode

The type of read sequence that the controller will follow for pipe read commands.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801C0

Offset: 0x1C0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rdwr_en_lo_cnt

Read/Write Enable low pulse width

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801F0

Offset: 0x1F0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x12				

rdwr_en_lo_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles that read or write enable will kept low to meet the min Trp/Twp parameter of the device. The value in this register plus rdwr_en_hi_cnt register value should meet the min cycle time of the device connected. The default value is calculated assuming the max nand_mp_clk time period of 4ns to work with ONFI Mode 0 mode of 100ns device cycle time. This assumes a 1x/4x clocking scheme.	RW	0x12

rdwr_en_hi_cnt

Read/Write Enable high pulse width

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80200

Offset: 0x200

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0xC				

rdwr_en_hi_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles that read or write enable will kept high to meet the min Treh/Tweh parameter of the device. The value in this register plus rdwr_en_lo_cnt register value should meet the min cycle time of the device connected. The default value is calculated assuming the max nand_mp_clk time period of 4ns to work with ONFI Mode 0 mode of 100ns device cycle time. This assumes a 1x/4x clocking scheme.	RW	0xC

max_rd_delay

Max round trip read data delay for data capture

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80210

Offset: 0x210

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												value			
												RW 0x0			

max_rd_delay Fields

Bit	Name	Description	Access	Reset
3:0	value	Number of nand_mp_clk cycles after generation of feedback nand_mp_clk pulse when it is safe to synchronize received data to nand_mp_clk domain. Data should have been registered with nand_mp_clk and stable by the time max_rd_delay cycles has elapsed. A default value of zero will mean a value of nand_mp_clk multiple minus one.	RW	0x0

cs_setup_cnt

Chip select setup time

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80220

Offset: 0x220

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x3				

cs_setup_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles required for meeting chip select setup time. This register refers to device timing parameter Tcs. The value in this registers reflects the extra setup cycles for chip select before read/write enable signal is set low. The default value is calculated for ONFI Timing mode 0 Tcs = 70ns and maximum nand_mp_clk period of 4ns for 1x/4x clock multiple for 16ns cycle time device. Please refer to Figure 3.3 for the relationship between the cs_setup_cnt and rdwr_en_lo_cnt values.	RW	0x3

spare_area_skip_bytes

Spare area skip bytes

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80230

Offset: 0x230

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x0				

spare_area_skip_bytes Fields

Bit	Name	Description	Access	Reset
5:0	value	Number of bytes to skip from start of spare area before last ECC sector data starts. The bytes will be written with the value programmed in the spare_area_marker register. This register could be potentially used to preserve the bad block marker in the spare area by marking it good. The default value is zero which means no bytes will be skipped and last ECC sector will start from the beginning of spare area.	RW	0x0

spare_area_marker

Spare area marker value

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80240

Offset: 0x240

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0xFFFF															

spare_area_marker Fields

Bit	Name	Description	Access	Reset
15:0	value	The value that will be written in the spare area skip bytes. This value will be used by controller while in the MAIN mode of data transfer. Only the least-significant 8 bits of the field value are used.	RW	0xFFFF

devices_connected

Number of Devices connected on one bank

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80250

Offset: 0x250

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													value RW 0x0		

devices_connected Fields

Bit	Name	Description	Access	Reset
2:0	value	Indicates the number of devices connected to a bank. At reset, the value loaded is the maximum possible devices that could be connected in this configuration.	RW	0x0

die_mask

Indicates the die differentiator in case of NAND devices with stacked dies.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80260

Offset: 0x260

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value RW 0x0					

die_mask Fields

Bit	Name	Description	Access	Reset
7:0	value	The die_mask register information will be used for devices having address restrictions. For example, in certain Samsung devices, when the first address in a two-plane command is being sent, it is expected that the address is all zeros. But if the NAND device internally has multiple dies stacked, the die information (MSB of final row address) has to be sent. The value programmed in this register will be used to mask the address while sending out the last row address.	RW	0x0

first_block_of_next_plane

The starting block address of the next plane in a multi plane device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80270

Offset: 0x270

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value															
RW 0x1															

first_block_of_next_plane Fields

Bit	Name	Description	Access	Reset
15:0	value	This values informs the controller of the plane structure of the device. In case the device is a multi plane device and the value here is 1, the controller understands that the next plane starts from Block number 1 and in conjunction with the number of planes parameter can decide upon the distribution of blocks in a plane in the device.	RW	0x1

write_protect

This register is used to control the assertion/de-assertion of the WP# pin to the device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80280

Offset: 0x280

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag
															RW 0x1

write_protect Fields

Bit	Name	Description	Access	Reset
0	flag	When the controller is in reset, the WP# pin is always asserted to the device. Once the reset is removed, the WP# is de-asserted. The software will then have to come and program this bit to assert/de-assert the same. [list][*]1 - Write protect de-assert [*]0 - Write protect assert[/list]	RW	0x1

re_2_re

Timing parameter between re high to re low (Trhz) for the next bank

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80290

Offset: 0x290

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value					
										RW 0x32					

re_2_re Fields

Bit	Name	Description	Access	Reset
5:0	value	Signifies the number of bus interface nand_mp_clk clocks that should be introduced between read enable going high to a bank to the read enable going low to the next bank. The number of clocks is the function of device parameter Trhz and controller clock frequency.	RW	0x32

por_reset_count

The number of cycles the controller waits after reset to issue the first RESET command to the device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB802A0

Offset: 0x2A0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value															
RW 0x13B															

por_reset_count Fields

Bit	Name	Description	Access	Reset
15:0	value	The controller waits for this number of cycles before issuing the first RESET command to the device. The number in this register is multiplied internally by 16 in the controller to form the final reset wait count.	RW	0x13B

watchdog_reset_count

The number of cycles the controller waits before flagging a watchdog timeout interrupt.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB802B0

Offset: 0x2B0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7	cmd_ dma	Not implemented.	RO	0x0
6	dma	if set, DATA-DMA is present in hardware.	RO	0x1
1:0	n_banks	Maximum number of banks supported by hardware. This is an encoded value. [list][*]0 - Two banks [*]1 - Four banks [*]2 - Eight banks [*]3 - Sixteen banks[/ list]	RO	0x1

Interrupt and Status Registers Register Descriptions

Contains interrupt and status registers of controller accessible by software.

Offset: 0x400

transfer_mode on page 13-80

Current data transfer mode is Main only, Spare only or Main+Spare. This information is per bank.

intr_status0 on page 13-80

Interrupt status register for bank 0

intr_en0 on page 13-82

Enables corresponding interrupt bit in interrupt register for bank 0

page_cnt0 on page 13-83

Decrementing page count bank 0

err_page_addr0 on page 13-84

Erred page address bank 0

err_block_addr0 on page 13-84

Erred block address bank 0

intr_status1 on page 13-85

Interrupt status register for bank 1

intr_en1 on page 13-86

Enables corresponding interrupt bit in interrupt register for bank 1

page_cnt1 on page 13-88

Decrementing page count bank 1

err_page_addr1 on page 13-89

Erred page address bank 1

err_block_addr1 on page 13-89

Erred block address bank 1

intr_status2 on page 13-90

Interrupt status register for bank 2

intr_en2 on page 13-91

Enables corresponding interrupt bit in interrupt register for bank 2

page_cnt2 on page 13-93

Decrementing page count bank 2

err_page_addr2 on page 13-93

Erred page address bank 2

err_block_addr2 on page 13-94

Erred block address bank 2

intr_status3 on page 13-94

Interrupt status register for bank 3

intr_en3 on page 13-96

Enables corresponding interrupt bit in interrupt register for bank 3

page_cnt3 on page 13-97

Decrementing page count bank 3

[err_page_addr3](#) on page 13-98

Erred page address bank 3

[err_block_addr3](#) on page 13-98

Erred block address bank 3

transfer_mode

Current data transfer mode is Main only, Spare only or Main+Spare. This information is per bank.

intr_status0 Fields

Bit	Name	Description	Access	Reset
15	page_xfer_inc	For every page of data transfer to or from the device, this bit will be set.	RW	0x0
14	pipe_cmd_err	A pipeline command sequence has been violated. This occurs when Map 01 page read/write address does not match the corresponding expected address from the pipeline commands issued earlier.	RW	0x0
13	rst_comp	Controller has finished reset and initialization process	RW	0x0
12	INT_act	R/B pin of device transitioned from low to high	RW	0x0
11	unsup_cmd	An unsupported command was received. This interrupt is set when an invalid command is received, or when a command sequence is broken.	RW	0x0
10	locked_blk	The address to program or erase operation is to a locked block and the operation failed due to this reason	RW	0x0
9	pipe_cpybck_cmd_comp	A pipeline command or a copyback bank command has completed on this particular bank	RW	0x0
8	erase_comp	Device erase operation complete	RW	0x0
7	program_comp	Device finished the last issued program command.	RW	0x0
6	load_comp	Device finished the last issued load command.	RW	0x0

Bit	Name	Description	Access	Reset
5	erase_fail	Erase failure occurred in the device on issuance of a erase command. err_block_addr and err_page_addr contain the block address and page address that failed erase operation.	RW	0x0
4	program_fail	Program failure occurred in the device on issuance of a program command. err_block_addr and err_page_addr contain the block address and page address that failed program operation.	RW	0x0
3	time_out	Watchdog timer has triggered in the controller due to one of the reasons like device not responding or controller state machine did not get back to idle	RW	0x0
2	dma_cmd_comp	Not implemented.	RW	0x0
0	ecc_uncor_err	Ecc logic detected uncorrectable error while reading data from flash device.	RW	0x0

intr_en0

Enables corresponding interrupt bit in interrupt register for bank 0

The hard processor system (HPS) provides a Secure Digital/Multimedia Card (SD/MMC) controller for interfacing to external SD and MMC flash cards, secure digital I/O (SDIO) devices, and Consumer Electronics Advanced Transport Architecture (CE-ATA) hard drives. The SD/MMC controller enables you to store boot images and boot the processor system from the removable flash card. You can also use the flash card to expand the on-board storage capacity for larger applications or user data. Other applications include interfacing to embedded SD (eSD) and embedded MMC (eMMC) nonremovable flash devices.

The SD/MMC controller is based on the Synopsys DesignWare Mobile Storage Host (SD/MMC controller) controller.

This document refers to SD/SDIO commands, which are documented in detail in the *Physical Layer Simplified Specification, Version 3.01* and the *SDIO Simplified Specification Version 2.00* described on the SD Association website.

ISO
9001:2008
Registered

- Supports HPS boot from mobile storage
- Supports the following standards or card types:
 - SD, including eSD—version 3.0
 - SDIO, including embedded SDIO (eSDIO)—version 3.0

Note: The previous items do not support SDR50, SDR104, and DDR50 modes.

 - CE-ATA—version 1.1
- Supports various types of multimedia cards, MMC version 4.41
 - MMC: 1-bit data bus
 - Reduced-size MMC (RSMMC): 1-bit and 4-bit data bus
 - MMCMobile: 1-bit data bus

Note: Does not support DDR mode.
- Supports embedded MMC (eMMC) version 4.41
 - 1-bit and 4-bit data bus

Note: Does not support DDR mode.
- Integrated descriptor-based direct memory access (DMA)
- Internal 4 KB receive and transmit FIFO buffer

The SD/MMC controller does not directly support voltage switching, card interrupts, or back-end power control of eSDIO card devices. However, you can connect these signals to general-purpose I/Os (GPIOs).

The SD/MMC controller does not contain a reset output as part of the external card interface. To reset the flash card device, consider using a general purpose output pin.

SD/MMC Controller Block Diagram and System Integration

The SD/MMC controller includes a bus interface unit (BIU) and a card interface unit (CIU). The BIU provides a slave interface for a host to access the control and status registers (CSRs). Additionally, this unit also provides independent FIFO buffer access through a DMA interface. The DMA controller is responsible for exchanging data between the system memory and FIFO buffer. The DMA registers are accessible by the host to control the DMA operation. The CIU supports the SD, MMC, and CE-ATA protocols on the controller, and provides clock management through the clock control block. The

⁽³⁶⁾ Because SD cards initially operate at 3.0 V and can switch to 1.8V after power-up and the BSEL values are constant during the boot process, transceivers are required to support level-shifting and isolation.

⁽³⁷⁾ SDR25 speed mode requires 1.8-V signaling. Note that even if a card supports UHS-I modes (for example SDR50, SDR104, DDR50) it can still communicate at the lower speeds (for example SDR12, SDR25).

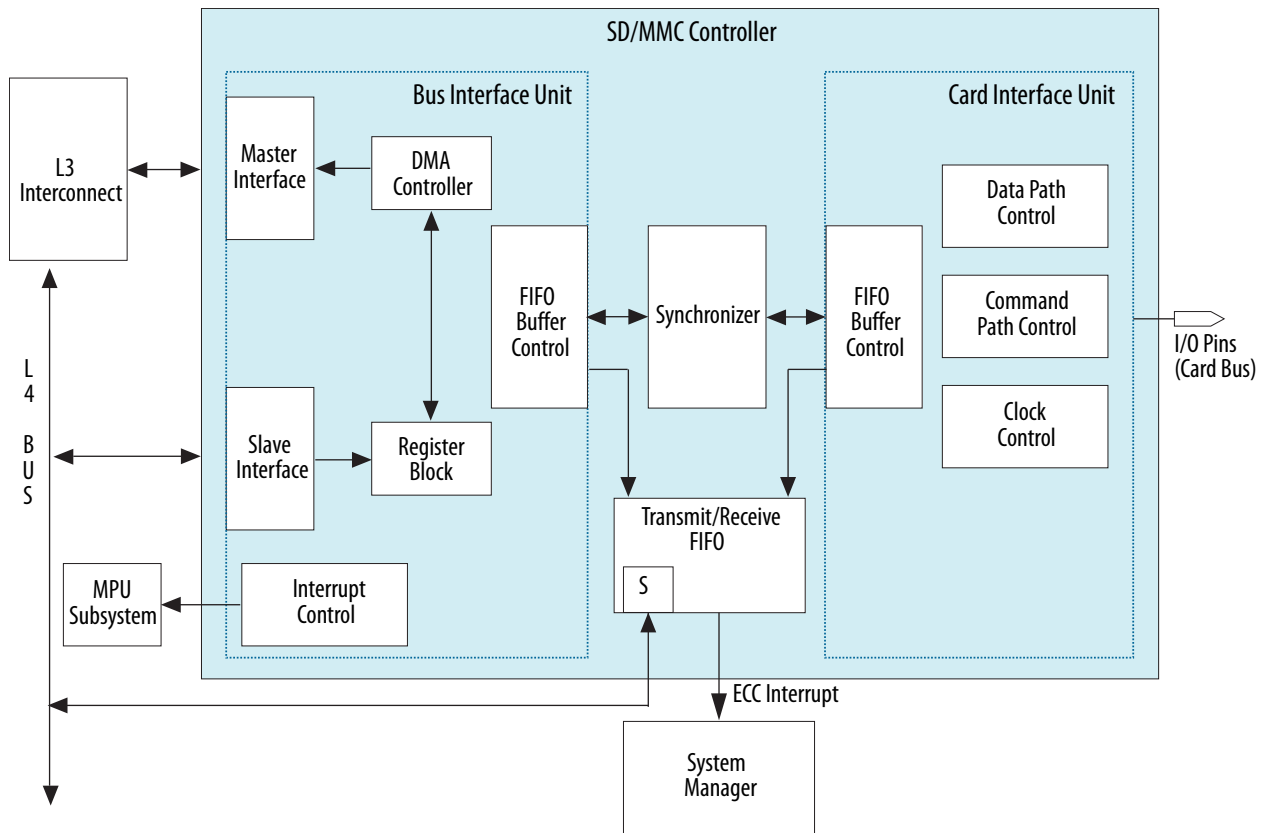

⁽³⁸⁾ Where supported, external transceivers are needed to switch the voltage.

⁽³⁹⁾ SPI mode is obsolete in the MMC 4.41 specification.

⁽⁴⁰⁾ Supports a maximum clock rate of 50 MHz instead of 52 MHz (specified in MMC specification).

interrupt control block for generating an interrupt connects to the generic interrupt controller in the ARM Cortex-A9 microprocessor unit (MPU) subsystem.

Figure 14-1: SD/MMC Controller Connectivity

Functional Description of the SD/MMC Controller

This section describes the SD/MMC controller components and how the controller operates.

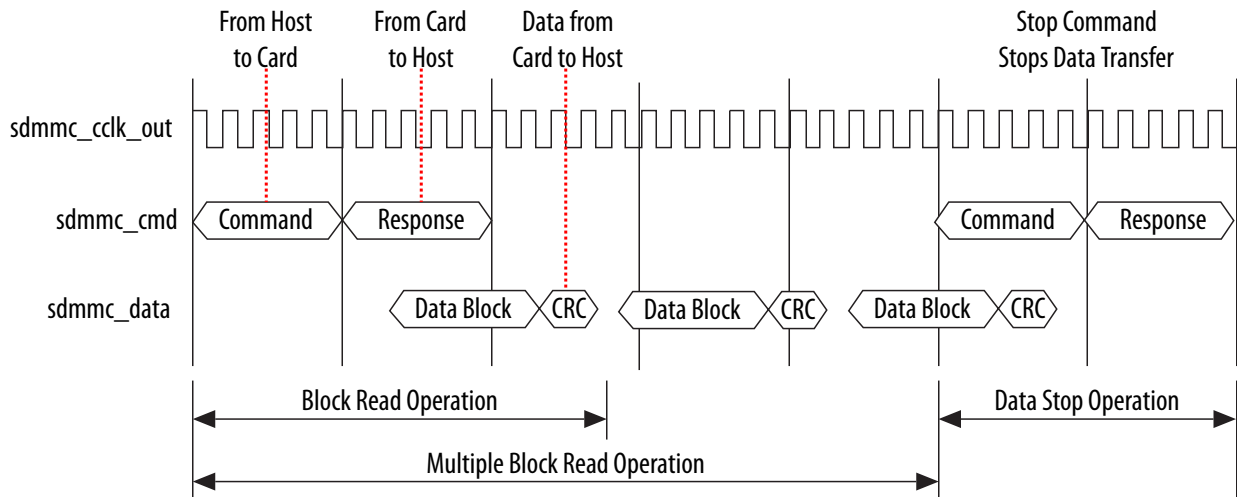

SD/MMC/CE-ATA Protocol

The SD/MMC/CE-ATA protocol is based on command and data bit streams that are initiated by a start bit and terminated by a stop bit. Additionally, the SD/MMC controller provides a reference clock and is the only master interface that can initiate a transaction.[†]

- Command—a token transmitted serially on the `CMD` pin that starts an operation.[†]
- Response—a token from the card transmitted serially on the `CMD` pin in response to certain commands.[†]
- Data—transferred serially using the data pins for data movement commands.[†]

In the following figure, the clock is a representative only and does not show the exact number of clock cycles.[†]

Figure 14-2: Multiple-Block Read Operation[†]

The following figure illustrates an example of a command token sent by the host in a multiple-block write operation.

Figure 14-3: Multiple-Block Write Operation[†]

BIU

The Bus Interface Unit (BIU) interfaces with the Card Interface Unit (CIU), and is connected to the level 3 (L3) interconnect and level 4 (L4) peripheral buses. The BIU consists of the following primary functional blocks, which are defined in the following sections:

- Slave interface
- Register block
- FIFO buffer
- Interrupt control
- Internal DMA controller

Slave Interface

The host processor accesses the SD/MMC controller registers and data FIFO buffers through the slave interface.

Register Block

The register block is part of the BIU and provides read and write access to the CSRs.[†]

All registers reside in the BIU clock domain, `l4_mp_clk`. When a command is sent to a card by setting the start command bit (`start_cmd`) of the command register (`cmd`) to 1, all relevant registers needed for the CIU operation are copied to the CIU block. During this time, software must not write to the registers that are transferred from the BIU to the CIU. The software must wait for the hardware to reset the `start_cmd` bit to 0 before writing to these registers again. The register unit has a hardware locking feature to prevent illegal writes to registers.[†]

Registers Locked Out Pending Command Acceptance

After a command start is issued by setting the `start_cmd` bit of the `cmd` register, the following registers cannot be rewritten until the command is accepted by the CIU:[†]

- Command (`cmd`)[†]
- Command argument (`cmdarg`)[†]
- Byte count (`bytcnt`)[†]
- Block size (`blksiz`)[†]
- Clock divider (`clkdiv`)[†]
- Clock enable (`ckena`)[†]
- Clock source (`clksrc`)[†]
- Timeout (`tmout`)[†]
- Card type (`ctype`)[†]

The hardware resets the `start_cmd` bit after the CIU accepts the command. If a host write to any of these registers is attempted during this locked time, the write is ignored and the hardware lock write error bit (`hle`) is set to 1 in the raw interrupt status register (`rintsts`). Additionally, if the interrupt is enabled and not masked for a hardware lock error, an interrupt is sent to the host.[†]

After a command is accepted, you can send another command to the CIU—which has a one-deep command queue—under the following conditions:[†]

- If the previous command is not a data transfer command, the new command is sent to the SD/MMC/CE-ATA card once the previous command completes.[†]
- If the previous command is a data transfer command and if the wait previous data complete bit (`wait_prvdata_complete`) of the `cmd` register is set to 1 for the new command, the new command is sent to the SD/MMC/CE-ATA card only when the data transfer completes.[†]
- If the `wait_prvdata_complete` bit is 0, the new command is sent to the SD/MMC/CE-ATA card as soon as the previous command is sent. Typically, use this feature to stop or abort a previous data transfer or query the card status in the middle of a data transfer.[†]

Interrupt Controller Unit

The interrupt controller unit generates an interrupt that depends on the `rintsts` register, the interrupt mask register (`intmask`), and the interrupt enable bit (`int_enable`) of the control register (`ctrl`). Once an interrupt condition is detected, the controller sets the corresponding interrupt bit in the `rintsts` register. The bit in the `rintsts` register remains set until the software clears the bit by writing a 1 to the interrupt bit; writing a 0 leaves the bit untouched.

The interrupt controller unit generates active high, level sensitive interrupts that are asserted only when at least one bit in the `rintsts` register is set to 1, the corresponding `intmask` register bit is 1, and the `int_enable` bit of the `ctrl` register is 1.

The `int_enable` bit of the `ctrl` register is cleared during a power-on reset, and the `intmask` register bits are set to 0x0000000, which masks all the interrupts.

Table 14-3: Interrupt Status Register Bits[†]

Bits	Interrupt	Description
16	SDIO Interrupts [†]	Interrupts from SDIO cards. [†]
15	End Bit Error (read)/Write no CRC (EBE) [†]	<p>Error in end-bit during read operation, or no data CRC received during write operation.[†]</p> <p>Note: For MMC CMD19, there may be no CRC status returned by the card. Hence, EBE is set for CMD19. The application should not treat this as an error.[†]</p>
14	Auto Command Done (ACD) [†]	<p>Stop/abort commands automatically sent by card unit and not initiated by host; similar to Command Done (CD) interrupt.[†]</p> <p>Recommendation: Software typically need not enable this for non CE-ATA accesses; Data Transfer Over (DTO) interrupt that comes after this interrupt determines whether data transfer has correctly completed. For CE-ATA accesses, if the software sets <code>send_auto_stop_ccsd</code> bit in the control register, then software should enable this bit.[†]</p>
13	Start Bit Error (SBE) [†]	Error in data start bit when data is read from a card. In 4-bit mode, if all data bits do not have start bit, then this error is set. [†]
12	Hardware Locked write Error (HLE) [†]	During hardware-lock period, write attempted to one of locked registers. [†]

Bits	Interrupt	Description
11	FIFO Underrun/Overrun Error (FRUN) [†]	<p>Host tried to push data when FIFO was full, or host tried to read data when FIFO was empty. Typically this should not happen, except due to error in software. [†]</p> <p>Card unit never pushes data into FIFO when FIFO is full, and pop data when FIFO is empty. [†]</p> <p>If IDMAC (Internal Direct Memory Access Controller) is enabled, FIFO underrun/overrun can occur due to a programming error on MSIZE and watermark values in FIFOTH register; for more information, refer to <i>Internal Direct Memory Access Controller (IDMAC)</i> section in the "Synopsys DesignWare Cores Mobile Storage Host Databook".[†]</p>
10	Data Starvation by Host Timeout (HTO) [†]	<p>To avoid data loss, card clock out (<code>cc1k_out</code>) is stopped if FIFO is empty when writing to card, or FIFO is full when reading from card. Whenever card clock is stopped to avoid data loss, data-starvation timeout counter is started with data-timeout value. This interrupt is set if host does not fill data into FIFO during write to card, or does not read from FIFO during read from card before timeout period. [†]</p> <p>Even after timeout, card clock stays in stopped state, with CIU state machines waiting. It is responsibility of host to push or pop data into FIFO upon interrupt, which automatically restarts <code>cc1k_out</code> and card state machines. [†]</p> <p>Even if host wants to send stop/abort command, it still must ensure to push or pop FIFO so that clock starts in order for stop/abort command to send on <code>cmd</code> signal along with data that is sent or received on data line. [†]</p>
9	Data Read Timeout (DRTO)/Boot Data Start (BDS) [†]	<ul style="list-style-type: none"> In Normal functioning mode: Data read timeout (DRTO) Data timeout occurred. Data Transfer Over (DTO) also set if data timeout occurs. [†] In Boot Mode: Boot Data Start (BDS) When set, indicates that SD/MMC controller has started to receive boot data from the card. A write to this register with a value of 1 clears this interrupt.[†]

Bits	Interrupt	Description
8	Response Timeout (RTO)/ Boot Ack Received (BAR) [†]	<ul style="list-style-type: none"> In Normal functioning mode: Response timeout (RTO) Response timeout occurred. Command Done (CD) also set if response timeout occurs. If command involves data transfer and when response times out, no data transfer is attempted by SD/MMC controller.[†] In Boot Mode: Boot Ack Received (BAR) When expect_boot_ack is set, on reception of a boot acknowledge pattern—0-1-0—this interrupt is asserted. A write to this register with a value of 1 clears this interrupt.[†]
7	Data CRC Error (DCRC) [†]	Received Data CRC does not match with locally-generated CRC in CIU; expected when a negative CRC is received. [†]
6	Response CRC Error (RCRC) [†]	Response CRC does not match with locally-generated CRC in CIU. [†]
5	Receive FIFO Data Request (RXDR) [†]	<p>Interrupt set during read operation from card when FIFO level is greater than Receive-Threshold level.[†]</p> <p>Recommendation: In DMA modes, this interrupt should not be enabled.[†]</p> <p>ISR, in non-DMA mode:</p> <pre>pop RX_WMark + 1 data from FIFO</pre> <p>[†]</p>
4	Transmit FIFO Data Request (TXDR) [†]	<p>Interrupt set during write operation to card when FIFO level reaches less than or equal to Transmit-Threshold level.[†]</p> <p>Recommendation: In DMA modes, this interrupt should not be enabled.[†]</p> <p>ISR in non-DMA mode: [†]</p> <pre>if (pending_bytes > \ (FIFO_DEPTH - TX_WMark))[†] push (FIFO_DEPTH - \ TX_WMark) data into FIFO[†] else[†] push pending_bytes data \ into FIFO[†]</pre>

Bits	Interrupt	Description
3	Data Transfer (DTO) [†]	<p>Data transfer completed, even if there is Start Bit Error or CRC error. This bit is also set when “read data-timeout” occurs or CCS is sampled from CE-ATA device.[†]</p> <p>Recommendation: In non-DMA mode, when data is read from card, on seeing interrupt, host should read any pending data from FIFO. In DMA mode, DMA controllers guarantee FIFO is flushed before interrupt.[†]</p> <p>Note: DTO bit is set at the end of the last data block, even if the device asserts MMC busy after the last data block.[†]</p>
2	Command Done (CD) [†]	<p>Command sent to card and received response from card, even if Response Error or CRC error occurs. Also set when response timeout occurs or CCSD sent to CE-ATA device.[†]</p>
1	Response Error (RE) [†]	<p>Error in received response set if one of following occurs:[†]</p> <ul style="list-style-type: none"> • Transmission bit != 0[†] • Command index mismatch[†] • End-bit != 1[†]
0	Card-Detect (CDT) [†]	<p>When one or more cards inserted or removed, this interrupt occurs. Software should read card-detect register (CDETECT, 0x50) to determine current card status.[†]</p> <p>Recommendation: After power-on and before enabling interrupts, software should read card detect register and store it in memory. When interrupt occurs, it should read card detect register and compare it with value stored in memory to determine which card(s) were removed/inserted. Before exiting ISR, software should update memory with new card-detect value.[†]</p>

Interrupt Setting and Clearing

The SDIO Interrupts, Receive FIFO Data Request, and Transmit FIFO Data Request interrupts are set by level-sensitive interrupt sources. Therefore, the interrupt source must be first cleared before you can reset the interrupt’s corresponding bit in the `rintsts` register to 0.[†]

For example, on receiving the Receive FIFO Data Request interrupt, the FIFO buffer must be emptied so that the FIFO buffer count is not greater than the RX watermark, which causes the interrupt to be triggered.†

The rest of the interrupts are triggered by single clock-pulse-width sources.†

FIFO Buffer

The SD/MMC controller has a 4 KB data FIFO buffer for storing transmit and receive data. The FIFO buffer memory supports error correction codes (ECCs). Both interfaces to the FIFO buffer support single and double bit error injection. The enable and error injection pins are inputs driven by the system manager and the status pins are outputs driven to the MPU subsystem.

The SD/MMC controller provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

Internal DMA Controller

The internal DMA controller has a CSR and a single transmit or receive engine, which transfers data from system memory to the card and vice versa. The controller uses a descriptor mechanism to efficiently move data from source to destination with minimal host processor intervention. You can set up the controller to interrupt the host processor in situations such as transmit and receive data transfer completion from the card, as well as other normal or error conditions. The DMA controller and the host driver communicate through a single data structure.†

The internal DMA controller transfers the data received from the card to the data buffer in the system memory, and transfers transmit data from the data buffer in the memory to the controller's FIFO buffer. Descriptors that reside in the system memory act as pointers to these buffers.†

A data buffer resides in the physical memory space of the system memory and consists of complete or partial data. The buffer status is maintained in the descriptor. Data chaining refers to data that spans multiple data buffers. However, a single descriptor cannot span multiple data buffers.†

A single descriptor is used for both reception and transmission. The base address of the list is written into the descriptor list base address register (`dbaddr`). A descriptor list is forward linked. The last descriptor can point back to the first entry to create a ring structure. The descriptor list resides in the physical memory address space of the host. Each descriptor can point to a maximum of two data buffers.†

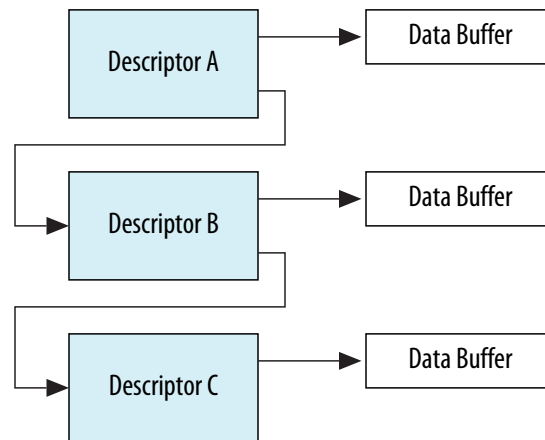

Internal DMA Controller Descriptors

The internal DMA controller uses these types of descriptor structures:†

- Dual-buffer structure—The distance between two descriptors is determined by the skip length value written to the descriptor skip length field (`ds1`) of the bus mode register (`bmod`).†

Figure 14-4: Dual-Buffer Descriptor Structure[†]

- Chain structure—Each descriptor points to a unique buffer, and to the next descriptor in a linked list.[†]

Figure 14-5: Chain Descriptor Structure[†]

Internal DMA Controller Descriptor Address

The descriptor address must be aligned to the 32-bit bus. Each descriptor contains 16 bytes of control and status information.[†]

Table 14-4: Descriptor Format

Name	Off-set	31	30	29:27	26	25:14	13	12:7	6	5	4	3	2	1	0
DES0	0	OWN	CES							ER	CH	FS	LD	DIC	—
DES1	4						BS2								BS1

[Internal DMA Controller Descriptor Fields](#) on page 14-13

Refer to this table for information about each of the bits of the descriptor.

Internal DMA Controller Descriptor Fields

The DES0 field in the internal DMA controller descriptor contains control and status information.

Table 14-5: Internal DMA Controller DES0 Descriptor Field†

Bits	Name	Description
31	OWN	When set to 1, this bit indicates that the descriptor is owned by the internal DMA controller. When this bit is set to 0, it indicates that the descriptor is owned by the host. The internal DMA controller resets this bit to 0 when it completes the data transfer.
30	Card Error Summary (CES)	The CES bit indicates whether a transaction error occurred. The CES bit is the logical OR of the following error bits in the <code>rintsts</code> register. <ul style="list-style-type: none"> • End-bit error (<code>ebe</code>) • Response timeout (<code>rto</code>) • Response CRC (<code>rcrc</code>) • Start-bit error (<code>sbe</code>) • Data read timeout (<code>drtto</code>) • Data CRC for receive (<code>dcrc</code>) • Response error (<code>re</code>)
29:6	Reserved	—
5	End of Ring (ER)	When set to 1, this bit indicates that the descriptor list reached its final descriptor. The internal DMA controller returns to the base address of the list, creating a descriptor ring. ER is meaningful for only a dual-buffer descriptor structure.
4	Second Address Chained (CH)	When set to 1, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set to 1, BS2 (DES1[25:13]) must be all zeros.

Bits	Name	Description
3	First Descriptor (FS)	When set to 1, this bit indicates that this descriptor contains the first buffer of the data. If the size of the first buffer is 0, next descriptor contains the beginning of the data.
2	Last Descriptor (LD)	When set to 1, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the data.
1	Disable Interrupt on Completion (DIC)	When set to 1, this bit prevents the setting of the TI/RI bit of the internal DMA controller status register (<code>idsts</code>) for the data that ends in the buffer pointed to by this descriptor.
0	Reserved	—

The DES1 descriptor field contains the buffer size.

Table 14-6: Internal DMA Controller DES1 Descriptor Field†

Bits	Name	Description
31:26	Reserved	—
25:13	Buffer 2 Size (BS2)	This field indicates the second data buffer byte size. The buffer size must be a multiple of four. When the buffer size is not a multiple of four, the resulting behavior is undefined. This field is not valid if DES0[4] is set to 1.
12:0	Buffer 1 Size (BS1)	Indicates the data buffer byte size, which must be a multiple of four bytes. When the buffer size is not a multiple of four, the resulting behavior is undefined. If this field is 0, the DMA ignores the buffer and proceeds to the next descriptor for a chain structure, or to the next buffer for a dual-buffer structure. If there is only one descriptor and only one buffer to be programmed, you need to use only buffer 1 and not buffer 2.

The DES2 descriptor field contains the address pointer to the data buffer.

Table 14-7: Internal DMA Controller DES2 Descriptor Field[†]

Bits	Name	Description
31:0	Buffer Address Pointer 1 (BAP1)	These bits indicate the physical address of the first data buffer. The internal DMA controller ignores DES2 [1:0], because it only performs 32-bit aligned accesses.

The DES3 descriptor field contains the address pointer to the next descriptor if the present descriptor is not the last descriptor in a chained descriptor structure or the second buffer address for a dual-buffer structure.[†]

Table 14-8: Internal DMA Controller DES3 Descriptor Field[†]

Bits	Name	Description
31:0	Buffer Address Pointer 2 (BAP2) or Next Descriptor Address	<p>These bits indicate the physical address of the second buffer when the dual-buffer structure is used. If the Second Address Chained (DES0[4]) bit is set to 1, this address contains the pointer to the physical memory where the next descriptor is present.</p> <p>If this is not the last descriptor, the next descriptor address pointer must be aligned to 32 bits. Bits 1 and 0 are ignored.</p>

Host Bus Burst Access

The internal DMA controller attempts to issue fixed-length burst transfers on the master interface if configured using the fixed burst bit (*fb*) of the *bmod* register. The maximum burst length is indicated and limited by the programmable burst length (*pbl*) field of the *bmod* register. When descriptors are being fetched, the master interface always presents a burst size of four to the interconnect.[†]

The internal DMA controller initiates a data transfer only when sufficient space to accommodate the configured burst is available in the FIFO buffer or the number of bytes to the end of transfer is less than the configured burst-length. When the DMA master interface is configured for fixed-length bursts, it transfers data using the most efficient combination of INCR4/8/16 and SINGLE transactions. If the DMA master interface is not configured for fixed length bursts, it transfers data using INCR (undefined length) and SINGLE transactions.[†]

Host Data Buffer Alignment

The transmit and receive data buffers in system memory must be aligned to a 32-bit boundary.

Buffer Size Calculations

The driver knows the amount of data to transmit or receive. For transmitting to the card, the internal DMA controller transfers the exact number of bytes from the FIFO buffer, indicated by the buffer size field of the DES1 descriptor field.[†]

If a descriptor is not marked as last (with the LD bit of the DES0 field set to 0) then the corresponding buffer(s) of the descriptor are considered full, and the amount of valid data in a buffer is accurately indicated by its buffer size field. If a descriptor is marked as last, the buffer might or might not be full, as

indicated by the buffer size in the DES1 field. The driver is aware of the number of locations that are valid.[†] The driver is expected to ignore the remaining, invalid bytes.

Internal DMA Controller Interrupts

Interrupts can be generated as a result of various events. The `idsts` register contains all the bits that might cause an interrupt. The internal DMA controller interrupt enable register (`idinten`) contains an enable bit for each of the events that can cause an interrupt to occur.[†]

There are two summary interrupts—the normal interrupt summary bit (`nis`) and the abnormal interrupt summary bit (`ais`)—in the `idsts` register.[†] The `nis` bit results from a logical OR of the transmit interrupt (`ti`) and receive interrupt (`ri`) bits in the `idsts` register. The `ais` bit is a logical OR result of the fatal bus error interrupt (`fbe`), descriptor unavailable interrupt (`du`), and card error summary interrupt (`ces`) bits in the `idsts` register.

Interrupts are cleared by writing a 1 to the corresponding bit position.[†] If a 0 is written to an interrupt's bit position, the write is ignored, and does not clear the interrupt. When all the enabled interrupts within a group are cleared, the corresponding summary bit is set to 0. When both the summary bits are set to 0, the interrupt signal is de-asserted.[†]

Interrupts are not queued. If another interrupt event occurs before the driver has responded to the previous interrupt, no additional interrupts are generated. For example, the `ri` bit of the `idsts` register indicates that one or more data has been transferred to the host buffer.[†]

An interrupt is generated only once for simultaneous, multiple events. The driver must scan the `idsts` register for the interrupt cause.[†] The final interrupt signal from the controller is a logical OR of the interrupts from the BIU and internal DMA controller.

Internal DMA Controller Functional State Machine†

The following list explains each state of the functional state machine:†

1. The internal DMA controller performs four accesses to fetch a descriptor.†
2. The DMA controller stores the descriptor information internally. If it is the first descriptor, the controller issues a FIFO buffer reset and waits until the reset is complete.†
3. The internal DMA controller checks each bit of the descriptor for the correctness. If bit mismatches are found, the appropriate error bit is set to 1 and the descriptor is closed by setting the OWN bit in the DES0 field to 1.†

The `rintsts` register indicates one of the following conditions:†

- Response timeout[†]
 - Response CRC error[†]
 - Data receive timeout[†]
 - Response error[†]
4. The DMA waits for the RX watermark to be reached before writing data to system memory, or the TX watermark to be reached before reading data from system memory. The RX watermark represents the number of bytes to be locally stored in the FIFO buffer before the DMA writes to memory. The TX watermark represents the number of free bytes in the local FIFO buffer before the DMA reads data from memory.[†]
 5. If the value of the programmable burst length (PBL) field is larger than the remaining amount of data in the buffer, single transfers are initiated. If dual buffers are being used, and the second buffer contains no data (buffer size = 0), the buffer is skipped and the descriptor is closed.[†]
 6. The OWN bit in descriptor is set to 0 by the internal DMA controller after the data transfer for one descriptor is completed. If the transfer spans more than one descriptor, the DMA controller fetches the next descriptor. If the transfer ends with the current descriptor, the internal DMA controller goes to idle state after setting the `ri` bit or the `ti` bit of the `idsts` register. Depending on the descriptor structure (dual buffer or chained), the appropriate starting address of descriptor is loaded. If it is the second data buffer of dual buffer descriptor, the descriptor is not fetched again.[†]

Abort During Internal DMA Transfer

If the host issues an SD/SDIO STOP_TRANSMISSION command (CMD12) to the card while data transfer is in progress, the internal DMA controller closes the present descriptor after completing the data transfer until a Data Transfer Over (DTO) interrupt is asserted. Once a STOP_TRANSMISSION command is issued, the DMA controller performs single burst transfers.[†]

- For a card write operation, the internal DMA controller keeps writing data to the FIFO buffer after fetching it from the system memory until a DTO interrupt is asserted. This is done to keep the card clock running so that the STOP_TRANSMISSION command is reliably sent to the card.[†]
- For a card read operation, the internal DMA controller keeps reading data from the FIFO buffer and writes to the system memory until a DTO interrupt is generated. This is required because DTO interrupt is not generated until and unless all the FIFO buffer data is emptied.[†]

Note: For a card write abort, only the current descriptor during which a STOP_TRANSMISSION command is issued is closed by the internal DMA controller. The remaining unread descriptors are not closed by the internal DMA controller.[†]

Note: For a card read abort, the internal DMA controller reads the data out of the FIFO buffer and writes them to the corresponding descriptor data buffers. The remaining unread descriptors are not closed.[†]

Fatal Bus Error Scenarios

A fatal bus error occurs due to an error response through the master interface. This error is a system error, so the software driver must not perform any further setup on the controller. The only recovery mechanism from such scenarios is to perform one of the following tasks:[†]

- Issue a reset to the controller through the reset manager.[†]
- Issue a program controller reset by writing to the controller reset bit (`controller_reset`) of the `ctrl` register.[†]

FIFO Buffer Overflow and Underflow

During normal data transfer conditions, FIFO buffer overflow and underflow does not occur. However, if there is a programming error, a FIFO buffer overflow or underflow can result. For example, consider the following scenarios.[†]

For transmit:[†]

- PBL=4[†]
- TX watermark = 1[†]

For these programming values, if the FIFO buffer has only one location empty, the DMA attempts to read four words from memory even though there is only one word of storage available. This results in a FIFO Buffer Overflow interrupt.[†]

For receive:[†]

- PBL=4[†]
- RX watermark = 1[†]

For these programming values, if the FIFO buffer has only one location filled, the DMA attempts to write four words, even though only one word is available. This results in a FIFO Buffer Underflow interrupt.[†]

The driver must ensure that the number of bytes to be transferred, as indicated in the descriptor, is a multiple of four bytes. For example, if the `bytCnt` register = 13, the number of bytes indicated in the descriptor must be rounded up to 16 because the length field must always be a multiple of four bytes.[†]

PBL and Watermark Levels

This table shows legal PBL and FIFO buffer watermark values for internal DMA controller data transfer operations.[†]

Table 14-9: PBL and Watermark Levels[†]

PBL (Number of transfers)	TX/RX FIFO Buffer Watermark Value
1	greater than or equal to 1
4	greater than or equal to 4
8	greater than or equal to 8
16	greater than or equal to 16
32	greater than or equal to 32
64	greater than or equal to 64
128	greater than or equal to 128
256	greater than or equal to 256

CIU

The Card Interface Unit (CIU) interfaces with the BIU and SD/MMC cards or devices. The host processor writes command parameters to the SD/MMC controller's BIU control registers and these parameters are then passed to the CIU. Depending on control register values, the CIU generates SD/MMC command and data traffic on the card bus according to the SD/MMC protocol. The control register values also decide whether the command and data traffic is directed to the CE-ATA card, and the SD/MMC controller controls the command and data path accordingly.[†]

The following list describes the CIU operation restrictions:[†]

- After a command is issued, the CIU accepts another command only to check read status or to stop the transfer.[†]
- Only one data transfer command can be issued at a time.[†]
- During an open-ended card write operation, if the card clock is stopped because the FIFO buffer is empty, the software must first fill the data into the FIFO buffer and start the card clock. It can then issue only an SD/SDIO STOP_TRANSMISSION (CMD12) command to the card.[†]
- During an SDIO/COMBO card transfer, if the card function is suspended and the software wants to resume the suspended transfer, it must first reset the FIFO buffer and start the resume command as if it were a new data transfer command.[†]
- When issuing SD/SDIO card reset commands (GO_IDLE_STATE, GO_INACTIVE_STATE or CMD52_reset) while a card data transfer is in progress, the software must set the stop abort command bit (`stop_abort_cmd`) in the `cmd` register to 1 so that the controller can stop the data transfer after issuing the card reset command.[†]
- If the card clock is stopped because the FIFO buffer is full during a card read, the software must read at least two FIFO buffer locations to start the card clock.[†]
- If CE-ATA card device interrupts are enabled (the `nIEN` bit is set to 0 in the ATA control register), a new `RW_BLK` command must not be sent to the same card device if there is a pending `RW_BLK` command in progress (the `RW_BLK` command used in this document is the `RW_MULTIPLE_BLOCK` MMC command defined by the CE-ATA specification). Only the Command Completion Signal Disable (CCSD) command can be sent while waiting for the Command Completion Signal (CCS).[†]
- For the same card device, a new command is allowed for reading status information, if interrupts are disabled in the CE-ATA card (the `nIEN` bit is set to 1 in the ATA control register).[†]
- Open-ended transfers are not supported for the CE-ATA card devices.[†]
- The `send_auto_stop` signal is not supported (software must not set the `send_auto_stop` bit in the `cmd` register) for CE-ATA transfers.[†]

The CIU consists of the following primary functional blocks:[†]

- Command path[†]
- Data path[†]
- Clock control[†]

Command Path

The command path performs the following functions:[†]

- Load card command parameters[†]
- Send commands to card bus[†]
- Receive responses from card bus[†]
- Send responses to BIU[†]
- Load clock parameters[†]
- Drives the P-bit on command pin[†]

A new command is issued to the controller by writing to the BIU registers and setting the `start_cmd` bit in the `cmd` register. The command path loads the new command (command, command argument, timeout) and sends an acknowledgement to the BIU.[†]

After the new command is loaded, the command path state machine sends a command to the card bus—including the internally generated seven-term CRC (CRC-7)—and receives a response, if any. The state machine then sends the received response and signals to the BIU that the command is done, and then waits for eight clock cycles before loading a new command. In CE-ATA data payload transfer (`RW_MULTIPLE_BLOCK`) commands, if the card device interrupts are enabled (the `nIEN` bit is set to 0

in the ATA control register), the state machine performs the following actions after receiving the response:[†]

- Does not drive the P-bit; it waits for CCS, decodes and goes back to idle state, and then drives the P-bit.[†]
- If the host wants to send the CCSD command and if eight clock cycles are expired after the response, it sends the CCSD pattern on the command pin.[†]

Load Command Parameters

Commands or responses are loaded in the command path in the following situations:[†]

- New command from BIU—When the BIU sends a new command to the CIU, the `start_cmd` bit is set to 1 in the `cmd` register.[†]
- Internally-generated `send_auto_stop`—When the data path ends, the SD/SDIO STOP command request is loaded.[†]
- Interrupt request (IRQ) response with relative card address (RCA) 0x000—When the command path is waiting for an IRQ response from the MMC and a “send irq response” request is signaled by the BIU, the send IRQ request bit (`send_irq_response`) is set to 1 in the `ctrl` register.[†]

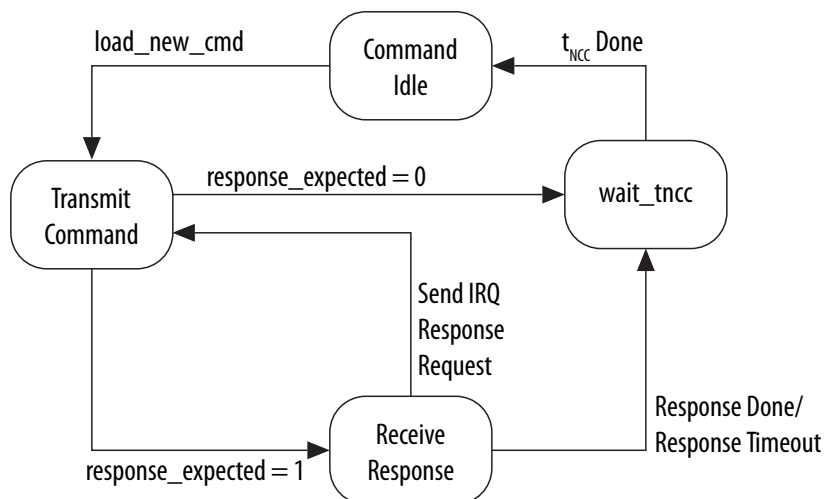

Loading a new command from the BIU in the command path depends on the following `cmd` register bit settings:[†]

- `update_clock_registers_only`—If this bit is set to 1 in the `cmd` register, the command path updates only the `clkena`, `clkdiv`, and `clksrc` registers. If this bit is set to 0, the command path loads the `cmd`, `cmdarg`, and `tmout` registers. It then processes the new command, which is sent to the card.[†]
- `wait_prvdata_complete`—If this bit is set to 1, the command path loads the new command under one of the following conditions:[†]
 - Immediately, if the data path is free (that is, there is no data transfer in progress), or if an open-ended data transfer is in progress (`bytcnt = 0`).[†]
 - After completion of the current data transfer, if a predefined data transfer is in progress.[†]

Send Command and Receive Response

After a new command is loaded in the command path (the `update_clock_registers_only` bit in the `cmd` register is set to 0), the command path state machine sends out a command on the card bus.[†]

Figure 14-6: Command Path State Machine[†]

The command path state machine performs the following functions, according to `cmd` register bit values:[†]

1. `send_initialization`—Initialization sequence of 80 clock cycles is sent before sending the command.[†]
2. `response_expected`—A response is expected for the command. After the command is sent out, the command path state machine receives a 48-bit or 136-bit response and sends it to the BIU. If the start bit of the card response is not received within the number of clock cycles (as set up in the `tmout` register), the `rto` bit and command done (`CD`) bit are set to 1 in the `rintsts` register, to signal to the BIU. If the response-expected bit is set to 0, the command path sends out a command and signals a response done to the BIU, which causes the `cmd` bit to be set to 1 in the `rintsts` register.[†]
3. `response_length`—If this bit is set to 1, a 136-bit long response is received; if it is set to 0, a 48-bit short response is received.[†]
4. `check_response_crc`—If this bit is set to 1, the command path compares CRC-7 received in the response with the internally-generated CRC-7. If the two do not match, the response CRC error is signaled to the BIU, that is, the `rcrc` bit is set to 1 in the `rintsts` register.[†]

Send Response to BIU

If the `response_expected` bit is set to 1 in the `cmd` register, the received response is sent to the BIU. Response register 0 (`resp0`) is updated for a short response, and the response register 3 (`resp3`), response register 2 (`resp2`), response register 1 (`resp1`), and `resp0` registers are updated on a long response, after which the `cmd` bit is set to 1 in the `rintsts` register. If the response is for an `AUTO_STOP` command sent by the CIU, the response is written to the `resp1` register, after which the auto command done bit (`acd`) is set to 1 in the `rintsts` register.[†]

The command path verifies the contents of the card response.

Table 14-10: Card Response Fields[†]

Field	Contents
Response transmission bit	0
Command index	Command index of the sent command
End bit	1

The command index is not checked for a 136-bit response or if the `check_response_crc` bit in the `cmd` register is set to 0. For a 136-bit response and reserved CRC 48-bit responses, the command index is reserved, that is, 0b111111.[†]

Related Information

www.sdcard.org

For more information about response values, refer to Physical Layer Simplified Specification, Version 3.01 as described on the SD Association website.

Driving P-bit to the CMD Pin

The command path drives a one-cycle pull-up bit (P-bit) to 1 on the `CMD` pin between two commands if a response is not expected. If a response is expected, the P-bit is driven after the response is received and before the start of the next command. While accessing a CE-ATA card device, for commands that expect a CCS, the P-bit is driven after the response only if the interrupts are disabled in the CE-ATA card (the `nIEN` bit is set to 1 in the ATA control register), that is, the CCS expected bit (`ccs_expected`) in the `cmd` register is set to 0. If the command expects the CCS, the P-bit is driven only after receiving the CCS.[†]

Polling the CCS

CE-ATA card devices generate the CCS to notify the host controller of the normal ATA command completion or ATA command termination. After receiving the response from the card, the command path state machine performs the functions illustrated in the following figure according to `cmd` register bit values.[†]

Figure 14-7: CE-ATA Command Path State Machine[†]

The above figure illustrates:

- Response end bit state—The state machine receives the end bit of the response from the card device. If the `ccs_expected` bit of the `cmd` register is set to 1, the state machine enters the wait CCS state.[†]
- Wait CCS—The state machine waits for the CCS from the CE-ATA card device. While waiting for the CCS, the following events can happen:[†]
 1. Software sets the send CCSD bit (`send_ccsd`) in the `ctrl` register, indicating not to wait for CCS and to send the CCSD pattern on the command line.[†]
 2. Receive the CCS on the CMD line.[†]
- Send CCSD command—Sends the CCSD pattern (0b00001) on the CMD line.[†]

CCS Detection and Interrupt to Host Processor

If the `ccs_expected` bit in the `cmd` register is set to 1, the CCS from the CE-ATA card device is indicated by setting the data transfer over bit (`dto`) in the `rintsts` register. The controller generates a DTO interrupt if this interrupt is not masked.[†]

For the `RW_MULTIPLE_BLOCK` commands, if the CE-ATA card device interrupts are disabled (the `nIEN` bit is set to 1 in the ATA control register)—that is, the `ccs_expected` bit is set to 0 in the `cmd` register—there are no CCSs from the card. When the data transfer is over—that is, when the requested number of bytes are transferred—the `dto` bit in the `rintsts` register is set to 1.[†]

CCS Timeout

If the command expects a CCS from the card device (the `ccs_expected` bit is set to 1 in the `cmd` register), the command state machine waits for the CCS and remains in the wait CCS state. If the CE-ATA card fails to send out the CCS, the host software must implement a timeout mechanism to free the command and

data path. The controller does not implement a hardware timer; it is the responsibility of the host software to maintain a software timer.[†]

In the event of a CCS timeout, the host must issue a CCSD command by setting the `send_ccsd` bit in the `ctrl` register. The controller command path state machine sends the CCSD command to the CE-ATA card device and exits to an idle state. After sending the CCSD command, the host must also send an SD/SDIO `STOP_TRANSMISSION` command to the CE-ATA card to abort the outstanding ATA command.[†]

Send CCSD Command

If the `send_ccsd` bit in the `ctrl` register is set to 1, the controller sends a CCSD pattern on the CMD line. The host can send the CCSD command while waiting for the CCS or after a CCS timeout happens.[†]

After sending the CCSD pattern, the controller sets the `cmd` bit in the `rintsts` register and also generates an interrupt to the host if the Command Done interrupt is not masked.[†]

Note: Within the CIU block, if the `send_ccsd` bit in the `ctrl` register is set to 1 on the same clock cycle as CCS is sampled, the CIU block does not send a CCSD pattern on the CMD line. In this case, the `dto` and `cmd` bits in the `rintsts` register are set to 1.[†]

Note: Due to asynchronous boundaries, the CCS might have already happened and the `send_ccsd` bit is set to 1. In this case, the CCSD command does not go to the CE-ATA card device and the `send_ccsd` bit is not set to 0. The host must reset the `send_ccsd` bit to 0 before the next command is issued.[†]

If the send auto stop CCSD (`send_auto_stop_ccsd`) bit in the `ctrl` register is set to 1, the controller sends an internally generated `STOP_TRANSMISSION` command (CMD12) after sending the CCSD pattern. The controller sets the `acd` bit in the `rintsts` register.[†]

I/O transmission delay (N_{ACIO} Timeout)

The host software maintains the timeout mechanism for handling the I/O transmission delay (N_{ACIO} cycles) time-outs while reading from the CE-ATA card device. The controller neither maintains any timeout mechanism nor indicates that N_{ACIO} cycles are elapsed while waiting for the start bit of a data token. The I/O transmission delay is applicable for read transfers using the `RW_REG` and `RW_BLK` commands; the `RW_REG` and `RW_BLK` commands used in this document refer to the `RW_MULTIPLE_REGISTER` and `RW_MULTIPLE_BLOCK` MMC commands defined by the CE-ATA specification.[†]

Note: After the N_{ACIO} timeout, the application must abort the command by sending the CCSD and `STOP` commands, or the `STOP` command. The Data Read Timeout (DRTO) interrupt might be set to 1 while a `STOP_TRANSMISSION` command is transmitted out of the controller, in which case the data read timeout boot data start bit (`bds`) and the `dto` bit in the `rintsts` register are set to 1.[†]

Data Path

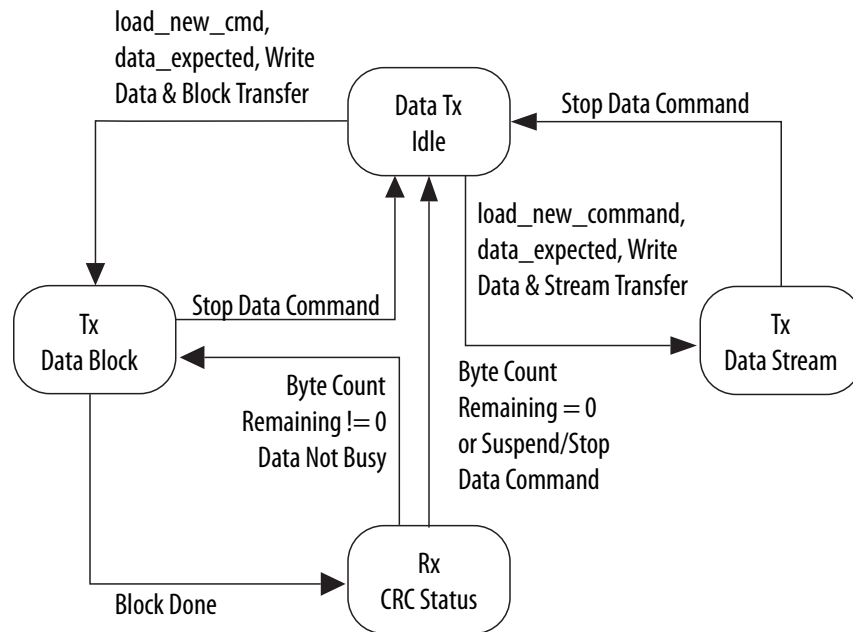

The data path block reads the data FIFO buffer and transmits data on the card bus during a write data transfer, or receives data and writes it to the FIFO buffer during a read data transfer. The data path loads new data parameters—data expected, read/write data transfer, stream/block transfer, block size, byte count, card type, timeout registers—whenever a data transfer command is not in progress. If the data transfer expected bit (`data_expected`) in the `cmd` register is set to 1, the new command is a data transfer command and the data path starts one of the following actions:[†]

- Transmits data if the read/write bit = 1[†]
- Receives data if read/write bit = 0[†]

Data Transmit

The data transmit state machine starts data transmission two clock cycles after a response for the data write command is received. This occurs even if the command path detects a response error or response CRC error. If a response is not received from the card because of a response timeout, data is not transmitted. Depending upon the value of the transfer mode bit (`transfer_mode`) in the `cmd` register, the data transmit state machine puts data on the card data bus in a stream or in blocks.[†]

Figure 14-8: Data Transmit State Machine[†]

Stream Data Transmit

If the `transfer_mode` bit in the `cmd` register is set to 1, the transfer is a stream-write data transfer. The data path reads data from the FIFO buffer from the BIU and transmits in a stream to the card data bus. If the FIFO buffer becomes empty, the card clock is stopped and restarted once data is available in the FIFO buffer.[†]

If the `bytcnt` register is reset to 0, the transfer is an open-ended stream-write data transfer. During this data transfer, the data path continuously transmits data in a stream until the host software issues an SD/SDIO STOP command. A stream data transfer is terminated when the end bit of the STOP command and end bit of the data match over two clock cycles.[†]

If the `bytcnt` register is written with a nonzero value and the `send_auto_stop` bit in the `cmd` register is set to 1, the STOP command is internally generated and loaded in the command path when the end bit of the STOP command occurs after the last byte of the stream write transfer matches. This data transfer can also terminate if the host issues a STOP command before all the data bytes are transferred to the card bus.[†]

Single Block Data

If the `transfer_mode` bit in the `cmd` register is set to 0 and the `bytcnt` register value is equal to the value of the `block_size` register, a single-block write-data transfer occurs. The data transmit state machine sends data in a single block, where the number of bytes equals the block size, including the internally-generated 16-term CRC (CRC-16).[†]

If the `ctype` register is set for a 1-bit, 4-bit, or 8-bit data transfer, the data is transmitted on 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and transmitted for 1, 4, or 8 data lines, respectively.[†]

After a single data block is transmitted, the data transmit state machine receives the CRC status from the card and signals a data transfer to the BIU. This happens when the `dto` bit in the `rintsts` register is set to 1.[†]

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register.[†]

Additionally, if the start bit of the CRC status is not received by two clock cycles after the end of the data block, a CRC status start-bit error (SBE) is signaled to the BIU by setting the `sbe` bit in the `rintsts` register.[†]

Multiple Block Data

A multiple-block write-data transfer occurs if the `transfer_mode` bit in the `cmd` register is set to 0 and the value in the `bytcnt` register is not equal to the value of the `block_size` register. The data transmit state machine sends data in blocks, where the number of bytes in a block equals the block size, including the internally-generated CRC-16 value.[†]

If the `ctype` register is set to 1-bit, 4-bit, or 8-bit data transfer, the data is transmitted on 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and transmitted on 1, 4, or 8 data lines, respectively.[†]

After one data block is transmitted, the data transmit state machine receives the CRC status from the card. If the remaining byte count becomes 0, the data path signals to the BIU that the data transfer is done. This happens when the `dto` bit in the `rintsts` register is set to 1.[†]

If the remaining data bytes are greater than zero, the data path state machine starts to transmit another data block.[†]

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register, and continues further data transmission until all the bytes are transmitted.[†]

If the CRC status start bit is not received by two clock cycles after the end of a data block, a CRC status SBE is signaled to the BIU by setting the `ebe` bit in the `rintsts` register and further data transfer is terminated.[†]

If the `send_auto_stop` bit is set to 1 in the `cmd` register, the SD/SDIO STOP command is internally generated during the transfer of the last data block, where no extra bytes are transferred to the card. The end bit of the STOP command might not exactly match the end bit of the CRC status in the last data block.[†]

If the block size is less than 4, 16, or 32 for card data widths of 1 bit, 4 bits, or 8 bits, respectively, the data transmit state machine terminates the data transfer when all the data is transferred, at which time the internally-generated STOP command is loaded in the command path.[†]

If the `bytcnt` is zero (the block size must be greater than zero) the transfer is an open-ended block transfer. The data transmit state machine for this type of data transfer continues the block-write data transfer until the host software issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command.[†]

Data Receive

The data-receive state machine receives data two clock cycles after the end bit of a data read command, even if the command path detects a response error or response CRC error. If a response is not received from the card because a response timeout occurs, the BIU does not receive a signal that the data transfer is complete. This happens if the command sent by the controller is an illegal operation for the card, which keeps the card from starting a read data transfer.[†]

If data is not received before the data timeout, the data path signals a data timeout to the BIU and an end to the data transfer done. Based on the value of the `transfer_mode` bit in the `cmd` register, the data-receive state machine gets data from the card data bus in a stream or block(s).[†]

Figure 14-9: Data Receive State Machine[†]

Stream Data Read

A stream-read data transfer occurs if the `transfer_mode` bit in the `cmd` register is set to 1, at which time the data path receives data from the card and writes it to the FIFO buffer. If the FIFO buffer becomes full, the card clock stops and restarts once the FIFO buffer is no longer full.[†]

An open-ended stream-read data transfer occurs if the `bytecnt` register is set to 0. During this type of data transfer, the data path continuously receives data in a stream until the host software issues an SD/SDIO STOP command. A stream data transfer terminates two clock cycles after the end bit of the STOP command.[†]

If the `bytecnt` register contains a nonzero value and the `send_auto_stop` bit in the `cmd` register is set to 1, a STOP command is internally generated and loaded into the command path, where the end bit of the STOP command occurs after the last byte of the stream data transfer is received. This data transfer can terminate if the host issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command before all the data bytes are received from the card.[†]

Single-block Data Read

If the `ctype` register is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and checked for 1, 4, or 8 data lines, respectively. If there

is a CRC-16 mismatch, the data path signals a data CRC error to the BIU. If the received end bit is not 1, the BIU receives an End-bit Error (EBE).[†]

Multiple-block Data Read

If the `transfer_mode` bit in the `cmd` register is clear and the value of the `bytcnt` register is not equal to the value of the `block_size` register, the transfer is a multiple-block read-data transfer. The data-receive state machine receives data in blocks, where the number of bytes in a block is equal to the block size, including the internally-generated CRC-16.[†]

If the `ctype` register is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and checked for 1, 4, or 8 data lines, respectively. After a data block is received, if the remaining byte count becomes zero, the data path signals a data transfer to the BIU.[†]

If the remaining data bytes are greater than zero, the data path state machine causes another data block to be received. If CRC-16 of a received data block does not match the internally-generated CRC-16, a data CRC error to the BIU and data reception continue further data transmission until all bytes are transmitted. Additionally, if the end of a received data block is not 1, data on the data path signals terminate the bit error to the CIU and the data-receive state machine terminates data reception, waits for data timeout, and signals to the BIU that the data transfer is complete.[†]

If the `send_auto_stop` bit in the `cmd` register is set to 1, the SD/SDIO STOP command is internally generated when the last data block is transferred, where no extra bytes are transferred from the card. The end bit of the STOP command might not exactly match the end bit of the last data block.[†]

If the requested block size for data transfers to cards is less than 4, 16, or 32 bytes for 1-bit, 4-bit, or 8-bit data transfer modes, respectively, the data-transmit state machine terminates the data transfer when all data is transferred, at which point the internally-generated STOP command is loaded in the command path. Data received from the card after that are then ignored by the data path.[†]

If the `bytcnt` register is 0 (the block size must be greater than zero), the transfer is an open-ended block transfer. For this type of data transfer, the data-receive state machine continues the block-read data transfer until the host software issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command.[†]

Auto-Stop

The controller internally generates an SD/SDIO STOP command and is loaded in the command path when the `send_auto_stop` bit in the `cmd` register is set to 1. The AUTO_STOP command helps to send an exact number of data bytes using a stream read or write for the MMC, and a multiple-block read or write for SD memory transfer for SD cards. The software must set the `send_auto_stop` bit according to the following details:[†]

The following list describes conditions for the AUTO_STOP command:[†]

- Stream-read for MMC with byte count greater than zero—The controller generates an internal STOP command and loads it into the command path so that the end bit of the STOP command is sent when the last byte of data is read from the card and no extra data byte is received. If the byte count is less than six (48 bits), a few extra data bytes are received from the card before the end bit of the STOP command is sent.[†]
- Stream-write for MMC with byte count greater than zero—The controller generates an internal STOP command and loads it into the command path so that the end bit of the STOP command is sent when the last byte of data is transmitted on the card bus and no extra data byte is transmitted. If the byte count is less than six (48 bits), the data path transmits the data last to meet these condition.[†]
- Multiple-block read memory for SD card with byte count greater than zero—If the block size is less than four (single-bit data bus), 16 (4-bit data bus), or 32 (8-bit data bus), the AUTO_STOP command is loaded in the command path after all the bytes are read. Otherwise, the STOP command is loaded in the command path so that the end bit of the STOP command is sent after the last data block is received.[†]
- Multiple-block write memory for SD card with byte count greater than zero—If the block size is less than three (single-bit data bus), 12 (4-bit data bus), or 24 (8-bit data bus), the AUTO_STOP command is loaded in the command path after all data blocks are transmitted. Otherwise, the STOP command is loaded in the command path so that the end bit of the STOP command is sent after the end bit of the CRC status is received.[†]
- Precaution for host software during auto-stop—When an AUTO_STOP command is issued, the host software must not issue a new command to the controller until the AUTO_STOP command is sent by the controller and the data transfer is complete. If the host issues a new command during a data transfer with the AUTO_STOP command in progress, an AUTO_STOP command might be sent after the new command is sent and its response is received. This can delay sending the STOP command, which transfers extra data bytes. For a stream write, extra data bytes are erroneous data that can corrupt the card data. If the host wants to terminate the data transfer before the data transfer is complete, it can issue an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command, in which case the controller does not generate an AUTO_STOP command.[†]

Auto-Stop Generation for MMC Cards

Table 14-11: Auto-Stop Generation for MMC Cards[†]

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Stream read	0	No	Open-ended stream
Stream read	>0	Yes	Auto-stop after all bytes transfer
Stream write	0	No	Open-ended stream
Stream write	>0	Yes	Auto-stop after all bytes transfer
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 is illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	Yes [†]	Pre-defined multiple block
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	Yes [†]	Pre-defined multiple block

Auto-Stop Generation for SD Cards**Table 14-12: Auto-Stop Generation for SD Cards[†]**

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	Yes	Auto-stop after all bytes transfer
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	Yes	Auto-stop after all bytes transfer

Auto-Stop Generation for SDIO Cards**Table 14-13: Auto-Stop Generation for SDIO Cards[†]**

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	No	Pre-defined multiple block
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	No	Pre-defined multiple block

Non-Data Transfer Commands that Use Data Path

Some SD/SDIO non-data transfer commands (commands other than read and write commands) also use the data path.[†]

⁽⁴¹⁾ The condition under which the transfer mode is set to block transfer and byte_count is equal to block size is treated as a single-block data transfer command for both MMC and SD cards. If byte_count = n*block_size (n = 2, 3, ...), the condition is treated as a predefined multiple-block data transfer command. In the case of an MMC card, the host software can perform a predefined data transfer in two ways: 1) Issue the CMD23 command before issuing CMD18/CMD25 commands to the card – in this case, issue CMD18/CMD25 commands without setting the send_auto_stop bit. 2) Issue CMD18/CMD25 commands without issuing CMD23 command to the card, with the send_auto_stop bit set. In this case, the multiple-block data transfer is terminated by an internally-generated auto-stop command after the programmed byte count.[†]

Table 14-14: Non-Data Transfer Commands and Requirements[†] - cmd Register Setup

	PROGRAM_CSD (CMD27)	SEND_WRITE_PROT (CMD30)	LOCK_UNLOCK (CMD42)	SD_STATUS (ACMD13)	SEND_NUM_WR_BLOCKS (ACMD22)	SEND_SCR (ACMD51)

Clock Control Block

The clock control block provides different clock frequencies required for SD/MMC/CE-ATA cards. The clock control block has one clock divider, which is used to generate different card clock frequencies.[†]

The clock frequency of a card depends on the following clock `ctrl` register settings:[†]

- `clkdiv` register—Internal clock dividers are used to generate different clock frequencies required for the cards. The division factor for the clock divider can be set by writing to the `clkdiv` register. The clock divider is an 8-bit value that provides a clock division factor from 1 to 510; a value of 0 represents a clock-divider bypass, a value of 1 represents a divide by 2, a value of 2 represents a divide by 4, and so on.[†]
- `clksrc` register—Set this register to 0 as clock is divided by clock divider 0.[†]
- `clkena` register—The `cclk_out` card output clock can be enabled or disabled under the following conditions:[†]
 - `cclk_out` is enabled when the `cclk_enable` bit in the `clkena` register is set to 1 and disabled when set to 0.[†]
 - Low-power mode can be enabled by setting the `cclk_low_power` bit of the `clkena` register to 1. If low-power mode is enabled to save card power, the `cclk_out` signal is disabled when the card is idle for at least eight card clock cycles. Low-power mode is enabled when a new command is loaded and the command path goes to a non-idle state.[†]

Under the following conditions, the card clock is stopped or disabled:[†]

- Clock can be disabled by writing to the `clkena` register.[†]
- When low-power mode is selected and the card is idle for at least eight clock cycles.[†]
- FIFO buffer is full, data path cannot accept more data from the card, and data transfer is incomplete—to avoid FIFO buffer overflow.[†]
- FIFO buffer is empty, data path cannot transmit more data to the card, and data transfer is incomplete—to avoid FIFO buffer underflow.[†]

⁽⁴²⁾ Num_bytes = Number of bytes specified as per the lock card data structure. Refer to the SD specification and the MMC specification.

⁽⁴³⁾ Num_bytes = Number of bytes specified as per the lock card data structure. Refer to the SD specification and the MMC specification.

Note: The card clock must be disabled through the `clkena` register before the host software changes the values of the `clkdiv` and `clksrc` registers.[†]

Error Detection

Errors can occur during card operations within the CIU in the following situations.

Response[†]

- Response timeout—did not receive the response expected with response start bit within the specified number of clock cycles in the timeout register.[†]
- Response CRC error—response is expected and check response CRC requested; response CRC-7 does not match with the internally-generated CRC-7.[†]
- Response error—response transmission bit is not 0, command index does not match with the command index of the send command, or response end bit is not 1.[†]

Data Transmit[†]

- No CRC status—during a write data transfer, if the CRC status start bit is not received for two clock cycles after the end bit of the data block is sent out, the data path performs the following actions:[†]
 - Signals no CRC status error to the BIU[†]
 - Terminates further data transfer[†]
 - Signals data transfer done to the BIU[†]
- Negative CRC—if the CRC status received after the write data block is negative (that is, not 0b010), the data path signals a data CRC error to the BIU and continues with the data transfer.[†]
- Data starvation due to empty FIFO buffer—if the FIFO buffer becomes empty during a write data transmission, or if the card clock stopped and the FIFO buffer remains empty for a data-timeout number of clock cycles, the data path signals a data-starvation error to the BIU and the data path continues to wait for data in the FIFO buffer.[†]

Data Receive

- Data timeout—during a read-data transfer, if the data start bit is not received before the number of clock cycles specified in the timeout register, the data path does the following action: [†]
 - Signals a data-timeout error to the BIU[†]
 - Terminates further data transfer[†]
 - Signals data transfer done to BIU[†]
- Data SBE—during a 4-bit or 8-bit read-data transfer, if the all-bit data line does not have a start bit, the data path signals a data SBE to the BIU and waits for a data timeout, after which it signals that the data transfer is done.[†]
- Data CRC error—during a read-data-block transfer, if the CRC-16 received does not match with the internally generated CRC-16, the data path signals a data CRC error to the BIU and continues with the data transfer.[†]
- Data EBE—during a read-data transfer, if the end bit of the received data is not 1, the data path signals an EBE to the BIU, terminates further data transfer, and signals to the BIU that the data transfer is done.[†]
- Data starvation due to FIFO buffer full—during a read data transmission and when the FIFO buffer becomes full, the card clock stops. If the FIFO buffer remains full for a data-timeout number of clock cycles, the data path signals a data starvation error to the BIU, by setting the data starvation host timeout bit (`hto`) in `rintsts` register to 1, and the data path continues to wait for the FIFO buffer to empty.[†]

Clocks

Table 14-18: SD/MMC Controller Clocks

Clock Name	Direction	Description
<code>l4_mp_clk</code>	In	Clock for SD/MMC controller BIU
<code>sdmmc_clk</code>	In	Clock for SD/MMC controller
<code>sdmmc_cclk_out</code>	Out	Generated output clock for card
<code>sdmmc_clk_divided</code>	Internal	Divide-by-four clock of <code>sdmmc_clk</code>
<code>sdmmc_sample_clk</code>	Internal	Phase-shifted clock of <code>sdmmc_clk_divided</code> used to sample the command and data from the card
<code>sdmmc_drv_clk</code>	Internal	Phase-shifted clock of <code>sdmmc_clk_divided</code> for controller to drive command and data to the card to meet hold time requirements

Figure 14-10: SD/MMC Controller Clock Connections

The `sdmmc_clk` clock from the clock manager is divided by four and becomes the `sdmmc_clk_divided` clock before passing to the phase shifters and the SD/MMC controller CIU. The phase shifters are used to generate the `sdmmc_drv_clk` and `sdmmc_sample_clk` clocks. These phase shifters provide up to eight phases shift which include 0, 45, 90, 135, 180, 225, 270, and 315 degrees. The `sdmmc_sample_clk` clock can be driven by the output from the phase shifter.

Note: The selections of phase shift degree and `sdmmc_sample_clk` source are done in the system manager. For information about setting the phase shift and selecting the source of the `sdmmc_sample_clk` clock, refer to the *Clock Setup* section within this document.

The controller generates the `sdmmc_cc1k_out` clock, which is driven to the card. For more information about the generation of the `sdmmc_cc1k_out` clock, refer to the *Clock Control Block* section within this document.

Resets

The SD/MMC controller has one reset signal. The reset manager drives this signal to the SD/MMC controller on a cold or warm reset.

Related Information

Reset Manager on page 3-1

Taking the SD/MMC Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Voltage Switching

This section describes the general steps to switch voltage level.

The SD/MMC cards support various operating voltages, for example 1.8V and 3.3V. If you have a card which is at 1.8V and you eject it and replace it with another card, which is 3.3V, then voltage switching is required.

In order to have the right voltage level to power the card, separate devices on the board are required: voltage translation transceiver and power regulator/supply. When the software is aware that voltage switching is needed, it notifies the power regulator that it needs to supply another voltage level to the card (i.e. switching between 1.8V and 3.3V).

Many SD cards have an option to signal at 1.8 or 3.3 V, however the initial power-up voltage requirement is 3.3V. To support these different voltage requirements, external transceivers are needed.

The general steps to switch voltage level requires you to use a SD/MMC voltage-translation transceiver in between the HPS and the SD/MMC card.

1. Power the HPS I/O pins for the SD/MMC controller to 3.3V.

Connect the same power supply to one of the transceiver voltage input pins.

2. Power the other transceiver voltage input pin with another power supply.

Connect this power supply with the SD/MMC card.

3. The SD/MMC will send predefined commands to check whether the card supports dual voltage.

Note: During this transaction, the software stops all SD/MMC activity.

The response from the card indicates whether dual voltage is supported.

Note: If the card does not support dual voltage, do not perform the remaining steps; otherwise, continue to the next step.

- Send a command to indicate that you want to switch to 1.8 V.

Then the GPIO on HPS sends a signal to the external power supply on the board notifying it to switch its voltage value.

- After voltage switching is completed, resume the SD/MMC activity.

Interface Signals

The following table shows the SD/MMC controller signals when they are routed to the FPGA instead of the HPS I/O pin multiplexer.

Note: The last five signals in the table are not routed to HPS I/O, but only to the FPGA.

Table 14-19: SD/MMC Controller Interface I/O Pins

Signal	Width	Direction	Description
sdmmc_cclk_out	1	Out	Clock from controller to the card
sdmmc_cmd	1	In/Out	Card command
sdmmc_pwren	1	Out	External device power enable
sdmmc_data	8	In/Out	Card data
sdmmc_cdn_i	1	In	Card detect signal
sdmmc_wp_i	1	In	Card write protect signal
sdmmc_vs_o	1	Out	Voltage switching between 3.3V and 1.8V
sdmmc_rstn_o	1	Out	Card reset signal
sdmmc_card_intn_i	1	In	Card interrupt signal

SD/MMC Controller Programming Model

Software and Hardware Restrictions[†]

Only one data transfer command should be issued at one time. For CE-ATA devices, if CE-ATA device interrupts are enabled ($nIEN=0$), only one `RW_MULTIPLE_BLOCK` command (`RW_BLK`) should be issued; no other commands (including a new `RW_BLK`) should be issued before the Data Transfer Over status is set for the outstanding `RW_BLK`.[†]

Before issuing a new data transfer command, the software should ensure that the card is not busy due to any previous data transfer command. Before changing the card clock frequency, the software must ensure that there are no data or command transfers in progress.[†]

If the card is enumerated in SDR12 or SDR25 mode, the application must program the `use_hold_reg` bit[29] in the `CMD` register to 1'b1.[†]

This programming should be done for all data transfer commands and non-data commands that are sent to the card. When the `use_hold_reg` bit is programmed to 1'b0, the SD/MMC controller bypasses the Hold Registers in the transmit path. The value of this bit should not be changed when a Command or Data Transfer is in progress.[†]

For more information on using the `use_hold_reg` and the implementation requirements for meeting the card input hold time, refer to the latest version of the Synopsys DesignWare Cores Mobile Storage Host Databook.

Avoiding Glitches in the Card Clock Outputs[†]

To avoid glitches in the card clock outputs (`sdmmc_clk_out`), the software should use the following steps when changing the card clock frequency:[†]

1. Before disabling the clocks, ensure that the card is not busy due to any previous data command. To determine this, check for 0 in bit 9 of the `STATUS` register.[†]
2. Update the Clock Enable register to disable all clocks. To ensure completion of any previous command before this update, send a command to the CIU to update the clock registers by setting:[†]

- `start_cmd` bit[†]
- "update clock registers only" bits[†]
- "wait_previous data complete"[†]

Note: Wait for the CIU to take the command by polling for 0 on the `start_cmd` bit.[†]

3. Set the `start_cmd` bit to update the Clock Divider and/or Clock Source registers, and send a command to the CIU in order to update the clock registers; wait for the CIU to take the command.[†]
4. Set `start_cmd` to update the Clock Enable register in order to enable the required clocks and send a command to the CIU to update the clock registers; wait for the CIU to take the command.[†]

Reading from a Card in Non-DMA Mode[†]

In non-DMA mode, while reading from a card, the Data Transfer Over (`RINTSTS[3]`) interrupt occurs as soon as the data transfer from the card is over. There still could be some data left in the FIFO, and the `RX_WMark` interrupt may or may not occur, depending on the remaining bytes in the FIFO. Software should read any remaining bytes upon seeing the Data Transfer Over (DTO) interrupt. While using the external DMA interface for reading from a card, the DTO interrupt occurs only after all the data is flushed to memory by the DMA Interface unit.[†]

Writing to a Card in External DMA Mode[†]

While writing to a card in external DMA mode, if an undefined-length transfer is selected by setting the Byte Count register to 0, the DMA logic will likely request more data than it will send to the card, since it has no way of knowing at which point the software will stop the transfer. The DMA request stops as soon as the DTO is set by the CIU.[†]

Software Issues a Controller_Reset Command†

If the software issues a `controller_reset` command by setting control register bit[0] to 1, all the CIU state machines are reset; the FIFO is not cleared. The DMA sends all remaining bytes to the host. In addition to a card-reset, if a FIFO reset is also issued, then:†

- Any pending DMA transfer on the bus completes correctly†
- DMA data read is ignored†
- Write data is unknown (x)†

Additionally, if `dma_reset` is also issued, any pending DMA transfer is abruptly terminated. When the DW-DMA/Non-DW-DMA is used, the DMA controller channel should also be reset and reprogrammed.†

If any of the previous data commands do not properly terminate, then the software should issue the FIFO reset in order to remove any residual data, if any, in the FIFO. After asserting the FIFO reset, you should wait until this bit is cleared.†

Data-Transfer Requirement Between the FIFO and Host†

One data-transfer requirement between the FIFO and host is that the number of transfers should be a multiple of the FIFO data width (`F_DATA_WIDTH`). For example, if `F_DATA_WIDTH = 32` and you want to write only 15 bytes to an `SD_MMC_CEATA` card (`BYTCNT`), the host should write 16 bytes to the FIFO or program the DMA to do 16-byte transfers, if external DMA mode is enabled. The software can still program the Byte Count register to only 15, at which point only 15 bytes will be transferred to the card. Similarly, when 15 bytes are read from a card, the host should still read all 16 bytes from the FIFO.†

It is recommended that you not change the FIFO threshold register in the middle of data transfers when DW-DMA/Non-DW-DMA mode is chosen.†

Initialization†

After the power and clock to the controller are stable, the controller active-low reset is asserted. The reset sequence initializes the registers, FIFO buffer pointers, DMA interface controls, and state machines in the controller.†

Figure 14-11: SD/MMC Controller Initialization Sequence[†]

Power-On Reset Sequence

Software must perform the following steps after the power-on-reset:

1. Before enabling power to the card, confirm that the voltage setting to the voltage regulator is correct.[†]
2. Enable power to the card by setting the power enable bit (`power_enable`) in the power enable register (`pwren`) to 1. Wait for the power ramp-up time before proceeding to the next step.[†]
3. Set the interrupt masks by resetting the appropriate bits to 0 in the `intmask` register.[†]
4. Set the `int_enable` bit of the `ctrl` register to 1.[†]

Note: Altera recommends that you write 0xFFFFFFFF to the `rintsts` register to clear any pending interrupts before setting the `int_enable` bit to 1.[†]

5. Discover the card stack according to the card type. For discovery, you must restrict the clock frequency to 400 kHz in accordance with SD/MMC/CE-ATA standards. For more information, refer to *Enumerated Card Stack*.[†]
6. Set the clock source assignments. Set the card frequency using the `clkdiv` and `clksrc` registers of the controller. For more information, refer to *Clock Setup*.[†]
7. The following common registers and fields can be set during initialization process:[†]

- The response timeout field (`response_timeout`) of the `tmout` register. A typical value is `0x40`.[†]
- The data timeout field (`data_timeout`) of the `tmout` register, highest of the following:[†]
 - $10 * N_{AC}$ [†]
 $N_{AC} = \text{card device total access time}^{\dagger}$
 $= 10 * ((TAAC * F_{OP}) + (100 * NSAC))^{\dagger}$
 where:[†]
 $TAAC = \text{Time-dependent factor of the data access time}^{\dagger}$
 $F_{OP} = \text{The card clock frequency used for the card operation}^{\dagger}$
 $NSAC = \text{Worst-case clock rate-dependent factor of the data access time}^{\dagger}$
 - Host FIFO buffer latency[†]
 On read: Time elapsed before host starts reading from a full FIFO buffer[†]
 On write: Time elapsed before host starts writing to an empty FIFO buffer[†]
- Debounce counter register (`debncce`). A typical debounce value is 25 ms.[†]
- TX watermark field (`tx_wmark`) of the FIFO threshold watermark register (`fifoth`). Typically, the threshold value is set to 512, which is half the FIFO buffer depth.[†]
- RX watermark field (`rx_wmark`) of the `fifoth` register. Typically, the threshold value is set to 511.[†]

These registers do not need to be changed with every SD/MMC/CE-ATA command. Set them to a typical value according to the SD/MMC/CE-ATA specifications.

Related Information

- [Clock Setup](#) on page 14-43
Refer to this section for information on setting the clock source assignments.
- [Enumerated Card Stack](#) on page 14-40
Refer to this section for information on discovering the card stack according to the card type.

Enumerated Card Stack

The card stack performs the following tasks:

- Discovers the connected card [†]
- Sets the relative Card Address Register (RCA) in the connected card[†]
- Reads the card specific information[†]
- Stores the card specific information locally[†]

The card connected to the controller can be an MMC, CE-ATA, SD or SDIO (including IO ONLY, MEM ONLY and COMBO) card.

Identifying the Connected Card Type

To identify the connected card type, the following discovery sequence is needed:

1. Reset the card width 1 or 4 bit (`card_width2`) and card width 8 bit (`card_width1`) fields in the `ctype` register to 0.
2. Identify the card type as SD, MMC, SDIO or SDIO-COMBO:

- a. Send an SD/SDIO `IO_SEND_OP_COND` (CMD5) command with argument 0 to the card.
- b. Read `resp0` on the controller. The response to the `IO_SEND_OP_COND` command gives the voltage that the card supports.
- c. Send the `IO_SEND_OP_COND` command, with the desired voltage window in the arguments. This command sets the voltage window and makes the card exit the initialization state.
- d. Check bit 27 in `resp0`:
 - If bit 27 is 0, the SDIO card is IO ONLY. In this case, proceed to [step 5](#).
 - If bit 27 is 1, the card type is SDIO COMBO. Continue with the following steps.
3. Go to [Card Type is Either SDIO COMBO or Still in Initialization](#) on page 14-41.
4. Go to [Determine if Card is a CE-ATA 1.1, CE-ATA 1.0, or MMC Device](#) on page 14-42.
5. At this point, the software has determined the card type as SD/SDHC, SDIO or SDIO-COMBO. Now it must enumerate the card stack according to the type that has been discovered.
6. Set the card clock source frequency to the frequency of identification clock rate, 400 KHz. Use one of the following discovery command sequences:
 - For an SD card or an SDIO memory section, send the following SD/SDIO command sequence:
 - `GO_IDLE_STATE`
 - `SEND_IF_COND`
 - `SD_SEND_OP_COND` (ACMD41)
 - `ALL_SEND_CID` (CMD2)
 - `SEND_RELATIVE_ADDR` (CMD3)
 - For an SDIO card, send the following command sequence:
 - `IO_SEND_OP_COND`
 - If the function count is valid, send the `SEND_RELATIVE_ADDR` command.
 - For an MMC, send the following command sequence:
 - `GO_IDLE_STATE`
 - `SEND_OP_COND` (CMD1)
 - `ALL_SEND_CID`
 - `SEND_RELATIVE_ADDR`
7. You can change the card clock frequency after discovery by writing a value to the `clkdiv` register that divides down the `sdmmc_clk` clock.

The following list shows typical clock frequencies for various types of cards:

- SD memory card, 25 MHz[†]
- MMC card device, 12.5 MHz[†]
- Full speed SDIO, 25 MHz[†]
- Low speed SDIO, 400 kHz[†]

Related Information

www.sdcard.org

To learn more about how SD technology works, visit the SD Association website.

Card Type is Either SDIO COMBO or Still in Initialization

Only continue with this step if the SDIO card type is COMBO or there is no response received from the previous `IO_SEND_OP_COND` command. Otherwise, skip to [step 5](#) of the *Identifying the Connected Card Type* section.

1. Send the SD/SDIO `SEND_IF_COND` (CMD8) command with the following arguments:

- Bit[31:12] = 0x0 (reserved bits)[†]
- Bit[11:8] = 0x1 (supply voltage value)[†]
- Bit[7:0] = 0xAA (preferred check pattern by SD memory cards compliant with SDIO Simplified Specification Version 2.00 and later.)[†]

Refer to *SDIO Simplified Specification Version 2.00* as described on the SD Association website.

- If a response is received to the previous SEND_IF_COND command, the card supports SD High-Capacity, compliant with *SD Specifications, Part 1, Physical Layer Simplified Specification Version 2.00*.
 - If no response is received, proceed to **the next decision statement**.
2. Send the SD_SEND_OP_COND (ACMD41) command with the following arguments:
 - Bit[31] = 0x0 (reserved bits)[†]
 - Bit[30] = 0x1 (high capacity status)[†]
 - Bit[29:25] = 0x0 (reserved bits)[†]
 - Bit[24] = 0x1 (S18R --supports voltage switching for 1.8V)[†]
 - Bit[23:0] = supported voltage range[†]
 - If the previous SD_SEND_OP_COND command receives a response, then the card type is SDHC. Otherwise, the card is MMC or CE-ATA. In either case, skip the following steps and proceed to **step 5** of the "Identifying the Connected Card Type" section.
 - If the initial SEND_IF_COND command does not receive a response, then the card does not support High Capacity SD2.0. Now, proceed to **step step 3**.
 3. Next, issue the GO_IDLE_STATE command followed by the SD_SEND_OP_COND command with the following arguments:
 - Bit[31] = 0x0 (reserved bits)[†]
 - Bit[30] = 0x0 (high capacity status)[†]
 - Bit[29:24] = 0x0 (reserved bits)[†]
 - Bit[23:0] = supported voltage range[†]

If a response is received to the previous SD_SEND_OP_COND command, the card is SD type. Otherwise, the card is MMC or CE-ATA.

Note: You must issue the SEND_IF_COND command prior to the first SD_SEND_OP_COND command, to initialize the High Capacity SD memory card. The card returns busy as a response to the SD_SEND_OP_COND command when any of the following conditions are true:

- The card executes its internal initialization process.
- A SEND_IF_COND command is not issued before the SD_SEND_OP_COND command.
- The ACMD41 command is issued. In the command argument, the Host Capacity Support (HCS) bit is set to 0, for a high capacity SD card.

Determine if Card is a CE-ATA 1.1, CE-ATA 1.0, or MMC Device

Use the following sequence to determine whether the card is a CE-ATA 1.1, CE-ATA 1.0, or MMC device:

Determine whether the card is a CE-ATA v1.1 card device by attempting to select ATA mode.

1. Send the SD/SDIO SEND_IF_COND command, querying byte 504 (S_CMD_SET) of the EXT_CSD register block in the external card.

If bit 4 is set to 1, the card device supports ATA mode.

2. Send the `SWITCH_FUNC` (CMD6) command, setting the ATA bit (bit 4) of the `EXT_CSD` register slice 191 (`CMD_SET`) to 1.

This command selects ATA mode and activates the ATA command set.

3. You can verify the currently selected mode by reading it back from byte 191 of the `EXT_CSD` register.
4. Skip to [step 5](#) of the *Identifying the Connected Card Type* section.

If the card device does not support ATA mode, it might be an MMC card or a CE-ATA v1.0 card.

Proceed to the [next section](#) to determine whether the card is a CE-ATA 1.0 card device or an MMC card device.

Determine whether the card is a CE-ATA 1.0 card device or an MMC card device by sending the `RW_REG` command.

If a response is received and the response data contains the CE-ATA signature, the card is a CE-ATA 1.0 card device. Otherwise, the card is an MMC card device.

Clock Setup

The following registers of the SD/MMC controller allow software to select the desired clock frequency for the card:

- `clksrc`
- `clkdiv`
- `clkena`

The controller loads these registers when it receives an update clocks command.

Changing the Card Clock Frequency

To change the card clock frequency, perform the following steps:

1. Before disabling the clocks, ensure that the card is not busy with any previous data command. To do so, verify that the `data_busy` bit of the status register (`status`) is 0.
2. Reset the `cclk_enable` bit of the `clkena` register to 0, to disable the card clock generation.
3. Reset the `clksrc` register to 0.
4. Set the following bits in the `cmd` register to 1:
 - `update_clk_regs_only`—Specifies the update clocks command[†]
 - `wait_prvdata_complete`—Ensures that clock parameters do not change until any ongoing data transfer is complete[†]
 - `start_cmd`—Initiates the command[†]
5. Wait until the `start_cmd` and `update_clk_regs_only` bits change to 0. There is no interrupt when the clock modification completes. The controller does not set the `command_done` bit in the `rintsts` register upon command completion. The controller might signal a hardware lock error if it already has another command in the queue. In this case, return to [Step 4](#).

For information about hardware lock errors, refer to *Interrupt and Error Handling*.

6. Reset the `sdmmc_clk_enable` bit to 0 in the `enable` register of the clock manager peripheral PLL group (`perpllgrp`).
7. In the control register (`ctrl`) of the SDMMC controller group (`sdmmcgrp`) in the system manager, set the drive clock phase shift select (`drvsel`) and sample clock phase shift select (`smp1sel`) bits to specify the required phase shift value.
8. Set the `sdmmc_clk_enable` bit in the `Enable` register of the clock manager `perpllgrp` group to 1.
9. Set the `clkdiv` register of the controller to the correct divider value for the required clock frequency.
10. Set the `cclk_enable` bit of the `clkena` register to 1, to enable the card clock generation.

You can also use the `clkena` register to enable low-power mode, which automatically stops the `sdmmc_cc1k_out` clock when the card is idle for more than eight clock cycles.

Related Information

[Interrupt and Error Handling](#) on page 14-70

Refer to this section for information about hardware lock errors.

Controller/DMA/FIFO Buffer Reset Usage

The following list shows the effect of reset on various parts in the SD/MMC controller:[†]

- Controller reset—resets the controller by setting the `controller_reset` bit in the `ctrl` register to 1. Controller reset resets the CIU and state machines, and also resets the BIU-to-CIU interface. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.[†]
- FIFO buffer reset—resets the FIFO buffer by setting the FIFO reset bit (`fifo_reset`) in the `ctrl` register to 1. FIFO buffer reset resets the FIFO buffer pointers and counters in the FIFO buffer. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.[†]
- DMA reset—resets the internal DMA controller logic by setting the DMA reset bit (`dma_reset`) in the `ctrl` register to 1, which immediately terminates any DMA transfer in progress. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.[†]

Note: Ensure that the DMA is idle before performing a DMA reset. Otherwise, the L3 interconnect might be left in an indeterminate state.[†]

Altera recommends setting the `controller_reset`, `fifo_reset`, and `dma_reset` bits in the `ctrl` register to 1 first, and then resetting the `rintsts` register to 0 using another write, to clear any resultant interrupt.

Enabling FIFO Buffer ECC

To protect the FIFO buffer data with ECC, you must enable the ECC feature before performing any operations with the SD/MMC controller. Perform the following steps to enable the FIFO buffer ECC feature:

1. Verify there are no commands committed to the controller.
2. Ensure that the FIFO buffer is initialized. Initialize the FIFO buffer by writing 0 to all 1024 FIFO buffer locations. A FIFO buffer write to any address from 0x200 to the maximum FIFO buffer size is valid.
3. Set the SDMMC RAM ECC single and double, correctable error interrupt status bits (`serrporta`, `derrporta`, `serrportb`, and `derrportb`) to 1 in the `sdmmc` register in the `eccgrp` group of the system manager, to clear any previously-detected ECC errors.
4. Reset the FIFO buffer by setting the `fifo_reset` bit to 1 in the `ctrl` register. This action resets pointers and counters in the FIFO buffer. This reset bit is self-clearing, so after issuing the reset, wait until the bit changes to 0.
5. Set the `en` bit in `sdmmc` register in `eccgrp` group of the system manager to 1, to enable ECC for the FIFO buffer in SD/MMC controller.

Non-Data Transfer Commands

To send any non-data transfer command, the software needs to write the `cmd` register and the `cmdarg` register with appropriate parameters. Using these two registers, the controller forms the command and sends it to the `CMD` pin. The controller reports errors in the command response through the error bits of the `rintsts` register.[†]

When a response is received—either erroneous or valid—the controller sets the `command_done` bit in the `rintsts` register to 1. A short response is copied to `resp0`, while a long response is copied to all four

response registers (*resp0*, *resp1*, *resp2*, and *resp3*).† For long responses, bit 31 of *resp3* represents the MSB and bit 0 of *resp0* represents the LSB.†

For basic and non-data transfer commands, perform the following steps:

1. Write the *cmdarg* register with the appropriate command argument parameter.†
2. Write the *cmd* register with the settings in *Register Settings for Non-Data Transfer Command*.†
3. Wait for the controller to accept the command. The *start_cmd* bit changes to 0 when the command is accepted.†

The following actions occur when the command is loaded into the controller:†

- If no previous command is being processed, the controller accepts the command for execution and resets the *start_cmd* bit in the *cmd* register to 0. If a previous command is being processed, the controller loads the new command in the command buffer.†
 - If the controller is unable to load the new command—that is, a command is already in progress, a second command is in the buffer, and a third command is attempted—the controller generates a hardware lock error.†
4. Check if there is a hardware lock error.†
 5. Wait for command execution to complete. After receiving either a response from a card or response timeout, the controller sets the *command_done* bit in the *rintsts* register to 1. Software can either poll for this bit or respond to a generated interrupt (if enabled).†
 6. Check if the response timeout boot acknowledge received (*bar*), *rcrc*, or *re* bit is set to 1. Software can either respond to an interrupt raised by these errors or poll the *re*, *rcrc*, and *bar* bits of the *rintsts* register. If no response error is received, the response is valid. If required, software can copy the response from the response registers.†

Note: Software cannot modify clock parameters while a command is being executed.†

Related Information

[cmd Register Settings for Non-Data Transfer Command†](#) on page 14-45

Refer to this table for information about Non-Data Transfer commands.

cmd Register Settings for Non-Data Transfer Command†

Table 14-20: Default

Parameter	Value	Comment
<i>start_cmd</i>	1	This bit resets itself to 0 after the command is committed.
<i>use_hold_reg</i>	1 or 0	Choose the value based on the speed mode used.
<i>update_clk_regs_only</i>	0	Indicates that the command is not a clock update command
<i>data_expected</i>	0	Indicates that the command is not a data command
<i>card_number</i>	1	For one card

Parameter	Value	Comment
cmd_index	Command Index	Set this parameter to the command number. For example, set to 8 for the SD/SDIO SEND_IF_COND (CMD8) command.
send_initialization	0 or 1	1 for card reset commands such as the SD/SDIO GO_IDLE_STATE command 0 otherwise
stop_abort_cmd	0 or 1	1 for a command to stop data transfer, such as the SD/SDIO STOP_TRANSMISSION command 0 otherwise
response_length	0 or 1	1 for R2 (long) response 0 for short response
response_expect	0 or 1	0 for commands with no response, such as SD/SDIO GO_IDLE_STATE, SET_DSR (CMD4), or GO_INACTIVE_STATE (CMD15). 1 otherwise

Table 14-21: User Selectable

Parameter	Value	Comment
wait_prvdata_complete	1	Before sending a command on the command line, the host must wait for completion of any data command already in process. Altera recommends that you set this bit to 1, unless the current command is to query status or stop data transfer when transfer is in progress.
check_response_crc	1 or 0	1 if the response includes a valid CRC, and the software is required to crosscheck the response CRC bits. 0 otherwise

Data Transfer Commands

Data transfer commands transfer data between the memory card and the controller. To issue a data command, the controller requires a command argument, total data size, and block size. Data transferred to or from the memory card is buffered by the controller FIFO buffer.[†]

Confirming Transfer State

Before issuing a data transfer command, software must confirm that the card is not busy and is in a transfer state, by performing the following steps:[†]

1. Issue an SD/SDIO SEND_STATUS (CMD13) command. The controller sends the status of the card as the response to the command.[†]
2. Check the card's busy status.[†]
3. Wait until the card is not busy.[†]
4. Check the card's transfer status. If the card is in the stand-by state, issue an SD/SDIO SELECT/DESELECT_CARD (CMD7) command to place it in the transfer state.[†]

Busy Signal After CE-ATA RW_BLK Write Transfer

During CE-ATA RW_BLK write transfers, the MMC busy signal might be asserted after the last block. If the CE-ATA card device interrupt is disabled (the nIEN bit in the card device's ATA control register is set to 1), the `dto` bit in the `rintsts` register is set to 1 even though the card sends MMC BUSY. The host cannot issue the CMD60 command to check the ATA busy status after a CMD61 command. Instead, the host must perform one of the following actions:[†]

- Issue the SEND_STATUS command and check the MMC busy status before issuing a new CMD60 command[†]
- Issue the CMD39 command and check the ATA busy status before issuing a new CMD60 command[†]

For the data transfer commands, software must set the `ctype` register to the bus width that is programmed in the card.[†]

Data Transfer Interrupts

The controller generates an interrupt for different conditions during data transfer, which are reflected in the following `rintsts` register bits:[†]

1. `dto`—Data transfer is over or terminated. If there is a response timeout error, the controller does not attempt any data transfer and the Data Transfer Over bit is never set.[†]
2. Transmit FIFO data request bit (`txdr`)—The FIFO buffer threshold for transmitting data is reached; software is expected to write data, if available, into the FIFO buffer.[†]
3. Receive FIFO data request bit (`rxdr`)—The FIFO buffer threshold for receiving data is reached; software is expected to read data from the FIFO buffer.[†]
4. `nto`—The FIFO buffer is empty during transmission or is full during reception. Unless software corrects this condition by writing data for empty condition, or reading data for full condition, the controller cannot continue with data transfer. The clock to the card is stopped.[†]
5. `bds`—The card has not sent data within the timeout period.[†]
6. `dcrc`—A CRC error occurred during data reception.[†]
7. `sbe`—The start bit is not received during data reception.[†]
8. `ebe`—The end bit is not received during data reception, or for a write operation. A CRC error is indicated by the card.[†]

`dcrc`, `sbe`, and `ebe` indicate that the received data might have errors. If there is a response timeout, no data transfer occurs.[†]

Single-Block or Multiple-Block Read

To implement a single-block or multiple-block read, the software performs the following steps:[†]

1. Write the data size in bytes to the `bytcnt` register. For a multi-block read, `bytcnt` must be a multiple of the block size.[†]
2. Write the block size in bytes to the `blksiz` register. The controller expects data to return from the card in blocks of size `blksiz`.[†]
3. If the read round trip delay, including the card delay, is greater than half of `sdmmc_clk_divided`, write to the card threshold control register (`cardthctl`) to ensure that the card clock does not stop in the

middle of a block of data being transferred from the card to the host. For more information, refer to *Card Read Threshold*.[†]

Note: If the card read threshold enable bit (`cardrdthren`) is 0, the host system must ensure that the RX FIFO buffer does not become full during a read data transfer by ensuring that the RX FIFO buffer is read at a rate faster than that at which data is written into the FIFO buffer. Otherwise, an overflow might occur.[†]

4. Write the `cmdarg` register with the beginning data address for the data read.[†]
5. Write the `cmd` register with the parameters listed in *cmd Register Settings for Single-Block and Multiple-Block Reads*. For SD and MMC cards, use the SD/SDIO `READ_SINGLE_BLOCK` (CMD17) command for a single-block read and the `READ_MULTIPLE_BLOCK` (CMD18) command for a multiple-block read. For SDIO cards, use the `IO_RW_EXTENDED` (CMD53) command for both single-block and multiple-block transfers. The command argument for (CMD53) is shown in the figure, below. After writing to the `cmd` register, the controller starts executing the command. When the command is sent to the bus, the Command Done interrupt is generated.[†]
6. Software must check for data error interrupts, reported in the `dcrc`, `bds`, `sbe`, and `ebe` bits of the `rintsts` register. If required, software can terminate the data transfer by sending an SD/SDIO STOP command.[†]
7. Software must check for host timeout conditions in the `rintsts` register:[†]
 - Receive FIFO buffer data request[†]
 - Data starvation from host—the host is not reading from the FIFO buffer fast enough to keep up with data from the card. To correct this condition, software must perform the following steps:[†]
 - Read the `fifo_count` field of the `status` register[†]
 - Read the corresponding amount of data out of the FIFO buffer[†]

In both cases, the software must read data from the FIFO buffer and make space in the FIFO buffer for receiving more data.[†]

8. When a DTO interrupt is received, the software must read the remaining data from the FIFO buffer.[†]

Figure 14-12: Command Argument for IO_RW_EXTENDED (CMD53)[†]

Related Information

- **Card Read Threshold** on page 14-67
Refer to this section for information about the thresholds for a card read.

cmd Register Settings for Single-Block and Multiple-Block Reads[†]

Table 14-22: cmd Register Settings for Single-Block and Multiple-Block Reads (Default)

Parameter	Value	Comment
start_cmd	1	This bit resets itself to 0 after the command is committed.
use_hold_reg	1 or 0	Choose the value based on speed mode used.
update_clk_regs_only	0	Does not need to update clock parameters
data_expected	1	Data command
card_number	1	For one card
transfer_mode	0	Block transfer

Parameter	Value	Comment
send_initialization	0	1 for a card reset command such as the SD/SDIO GO_IDLE_STATE command 0 otherwise
stop_abort_cmd	0	1 for a command to stop data transfer such as the SD/SDIO STOP_TRANSMISSION command 0 otherwise
send_auto_stop	0 or 1	Refer to <i>Auto Stop</i> for information about how to set this parameter.
read_write	0	Read from card
response_length	0	1 for R2 (long) response 0 for short response
response_expect	1 or 0	0 for commands with no response, such as SD/SDIO GO_IDLE_STATE, SET_DSR, and GO_INACTIVE_STATE. 1 otherwise

Table 14-23: cmd Register Settings for Single-Block and Multiple-Block Reads (User Selectable)

Parameter	Value	Comment
wait_prvdata_complete	1 or 0	0 - sends command to CIU immediately 1 - sends command after previous data transfer ends
check_response_crc	1 or 0	0 - Controller must not check response CRC 1 - Controller must check response CRC
cmd_index	Command Index	Set this parameter to the command number. For example, set to 17 or 18 for SD/SDIO READ_SINGLE_BLOCK (CMD17) or READ_MULTIPLE_BLOCK (CMD18)

Related Information

[Auto-Stop](#) on page 14-28

Refer to this table for information about setting the `send_auto_stop` parameter.

Single-Block or Multiple-Block Write

The following steps comprise a single-block or multiple-block write:

1. Write the data size in bytes to the `bytcnt` register. For a multi-block write, `bytcnt` must be a multiple of the block size.[†]
2. Write the block size in bytes to the `blksiz` register. The controller sends data in blocks of size `blksiz` each.[†]
3. Write the `cmdarg` register with the data address to which data must be written.[†]
4. Write data into the FIFO buffer. For best performance, the host software should write data continuously until the FIFO buffer is full.[†]
5. Write the `cmd` register with the parameters listed in *cmd Register Settings for Single-Block and Multiple-Block Write*. For SD and MMC cards, use the SD/SDIO WRITE_BLOCK (CMD24) command for a single-block write and the WRITE_MULTIPLE_BLOCK (CMD25) command for a multiple-block writes. For SDIO cards, use the IO_RW_EXTENDED command for both single-block and multiple-block transfers.[†]

After writing to the `cmd` register, the controller starts executing a command if there is no other command already being processed. When the command is sent to the bus, a Command Done interrupt is generated.[†]

6. Software must check for data error interrupts; that is, for `dcrc`, `bds`, and `ebe` bits of the `rintsts` register. If required, software can terminate the data transfer early by sending the SD/SDIO STOP command.[†]
7. Software must check for host timeout conditions in the `rintsts` register:[†]
 - Transmit FIFO buffer data request.[†]
 - Data starvation by the host—the controller wrote data to the card faster than the host could supply the data.[†]

In both cases, the software must write data into the FIFO buffer.[†]

There are two types of transfers: open-ended and fixed length.[†]

- Open-ended transfers—For an open-ended block transfer, the byte count is 0. At the end of the data transfer, software must send the STOP_TRANSMISSION command (CMD12).[†]
- Fixed-length transfers—The byte count is nonzero. You must already have written the number of bytes to the `bytcnt` register. The controller issues the STOP command for you if you set the `send_auto_stop` bit of the `cmd` register to 1. After completion of a transfer of a given number of bytes, the controller sends the STOP command. Completion of the AUTO_STOP command is reflected by the Auto Command Done interrupt. A response to the AUTO_STOP command is written to the `resp1` register. If software does not set the `send_auto_stop` bit in the `cmd` register to 1, software must issue the STOP command just like in the open-ended case.[†]

When the `dto` bit of the `rintsts` register is set, the data command is complete.[†]

cmd Register Settings for Single-Block and Multiple-Block Write

Table 14-24: cmd Register Settings for Single-Block and Multiple-Block Write (Default)[†]

Parameter	Value	Comment
<code>start_cmd</code>	1	This bit resets itself to 0 after the command is committed (accepted by the BIU).
<code>use_hold_reg</code>	1 or 0	Choose the value based on speed mode used.
<code>update_clk_regs_only</code>	0	Does not need to update clock parameters

Parameter	Value	Comment
data_expected	1	Data command
card_number	1	For one card
transfer_mode	0	Block transfer
send_initialization	0	Can be 1, but only for card reset commands such as SD/SDIO GO_IDLE_STATE
stop_abort_cmd	0	Can be 1 for commands to stop data transfer such as SD/SDIO STOP_TRANSMISSION
send_auto_stop	0 or 1	Refer to <i>Auto Stop</i> for information about how to set this parameter.
read_write	1	Write to card
response_length	0	Can be 1 for R2 (long) responses
response_expect	1	Can be 0 for commands with no response. For example, SD/SDIO GO_IDLE_STATE, SET_DSR, GO_INACTIVE_STATE etc.

Table 14-25: cmd Register Settings for Single-Block and Multiple-Block Write (User Selectable)[†]

Parameter	Value	Comment
wait_prvdata_complete	1	0—Sends command to the CIU immediately 1—Sends command after previous data transfer ends
check_response_crc	1	0—Controller must not check response CRC 1—Controller must check response CRC
cmd_index	Command Index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).

Related Information

[Auto-Stop](#) on page 14-28

Refer to this table for information about setting the `send_auto_stop` parameter.

Stream Read and Write

In a stream transfer, if the byte count is equal to 0, the software must also send the SD/SDIO STOP command. If the byte count is not 0, when a given number of bytes completes a transfer, the controller sends the STOP command automatically. Completion of this AUTO_STOP command is reflected by the

Auto_command_done interrupt. A response to an AUTO_STOP command is written to the `resp1` register. A stream transfer is allowed only for card interfaces with a 1-bit data bus.[†]

A stream read requires the same steps as the block read described in *Single-Block or Multiple-Block Read*, except for the following bits in the `cmd` register:[†]

- `transfer_mode` = 0x1 (for stream transfer)[†]
- `cmd_index` = 20 (SD/SDIO CMD20)[†]

A stream write requires the same steps as the block write mentioned in *Single-Block or Multiple-Block Write*, except for the following bits in the `cmd` register:[†]

- `transfer_mode` = 0x1 (for stream transfer)[†]
- `cmd_index` = 11 (SD/SDIO CMD11)[†]

Refer to this section for more information about a stream write.

Packed Commands

To reduce overhead, read and write commands can be packed in groups of commands—either all read or all write—that transfer the data for all commands in the group in one transfer on the bus. Use the SD/SDIO SET_BLOCK_COUNT (CMD23) command to state ahead of time how many blocks will be transferred. Then issue a single READ_MULTIPLE_BLOCK or WRITE_MULTIPLE_BLOCK command to read or write multiple blocks.[†]

- SET_BLOCK_COUNT—set block count (number of blocks transferred using the READ_MULTIPLE_BLOCK or WRITE_MULTIPLE_BLOCK command)[†]
- READ_MULTIPLE_BLOCK—multiple-block read command[†]
- WRITE_MULTIPLE_BLOCK—multiple-block write command[†]

Packed commands are organized in packets by the application software and are transparent to the controller.[†]

Related Information

www.jedec.org

For more information about packed commands, refer to JEDEC Standard No. 84-A441, available on the JEDEC website.

Transfer Stop and Abort Commands

This section describes stop and abort commands. The SD/SDIO STOP_TRANSMISSION command can terminate a data transfer between a memory card and the controller. The ABORT command can terminate an I/O data transfer for only an SDIO card.[†]

STOP_TRANSMISSION (CMD12)

The host can send the STOP_TRANSMISSION (CMD12) command on the CMD pin at any time while a data transfer is in progress. Perform the following steps to send the STOP_TRANSMISSION command to the SD/SDIO card device:[†]

1. Set the `wait_prvdata_complete` bit of the `cmd` register to 0.[†]
2. Set the `stop_abort_cmd` in the `cmd` register to 1, which ensures that the CIU stops.[†]

The `STOP_TRANSMISSION` command is a non-data transfer command.[†]

Related Information

[Non-Data Transfer Commands](#) on page 14-44

Refer to this section for information on the `STOP_TRANSMISSION` command.

ABORT

The ABORT command can only be used with SDIO cards. To abort the function that is transferring data, program the ABORT function number in the `ASx[2:0]` bits at address 0x06 of the card common control register (CCCR) in the card device, using the `IO_RW_DIRECT` (CMD52) command. The CCCR is located at the base of the card space 0x00 – 0xFF.[†]

Note: The ABORT command is a non-data transfer command.[†]

Related Information

[Non-Data Transfer Commands](#) on page 14-44

Refer to this section for information on the ABORT command.

Sending the ABORT Command

Perform the following steps to send the ABORT command to the SDIO card device:[†]

1. Set the `cmdarg` register to include the appropriate command argument parameters listed in *cmdarg Register Settings for SD/SDIO ABORT Command*.[†]
2. Send the `IO_RW_DIRECT` command by setting the following fields of the `cmd` register:[†]
 - Set the command index to 0x52 (`IO_RW_DIRECT`).[†]
 - Set the `stop_abort_cmd` bit of the `cmd` register to 1 to inform the controller that the host aborted the data transfer.[†]
 - Set the `wait_prvdata_complete` bit of the `cmd` register to 0.[†]
3. Wait for the `cmd` bit in the `rintsts` register to change to 1.[†]
4. Read the response to the `IO_RW_DIRECT` command (R5) in the response registers for any errors.[†]

For more information about response values, refer to the Physical Layer Simplified Specification, Version 3.01, available on the SD Association website.

cmdarg Register Settings for SD/SDIO ABORT Command[†]

Table 14-26: `cmdarg` Register Settings for SD/SDIO ABORT Command

Bits	Contents	Value
31	R/W flag	1
30:28	Function number	0, for access to the CCCR in the card device

Bits	Contents	Value
27	RAW flag	1, if needed to read after write
26	Don't care	-
25:9	Register address	0x06
8	Don't care	-
7:0	Write data	Function number to abort

Internal DMA Controller Operations

For better performance, you can use the internal DMA controller to transfer data between the host and the controller. This section describes the internal DMA controller's initialization process, and transmission sequence, and reception sequence.

Internal DMA Controller Initialization

To initialize the internal DMA controller, perform the following steps:[†]

- Set the required `bmod` register bits:[†]
 - If the internal DMA controller enable bit (`de`) of the `bmod` register is set to 0 during the middle of a DMA transfer, the change has no effect. Disabling only takes effect for a new data transfer command.[†]
 - Issuing a software reset immediately terminates the transfer. Prior to issuing a software reset, Altera recommends the host reset the DMA interface by setting the `dma_reset` bit of the `ctrl` register to 1.[†]
 - The `pb1` field of the `bmod` register is read-only and a direct reflection of the contents of the DMA multiple transaction size field (`dw_dma_multiple_transaction_size`) in the `fifo` register.[†]
 - The `fb` bit of the `bmod` register has to be set appropriately for system performance.[†]
- Write to the `idinten` register to mask unnecessary interrupt causes according to the following guidelines:[†]
 - When a Descriptor Unavailable interrupt is asserted, the software needs to form the descriptor, appropriately set its own bit, and then write to the poll demand register (`pldmnd`) for the internal DMA controller to re-fetch the descriptor.[†]
 - It is always appropriate for the software to enable abnormal interrupts because any errors related to the transfer are reported to the software.[†]
- Populate either a transmit or receive descriptor list in memory. Then write the base address of the first descriptor in the list to the internal DMA controller's descriptor list base address register (`dbaddr`). The DMA controller then proceeds to load the descriptor list from memory. *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences* describe this step in detail.[†]

Related Information

- [Internal DMA Controller Transmission Sequences](#) on page 14-56
Refer to this section for information about the Internal DMA Controller Transmission Sequences.
- [Internal DMA Controller Reception Sequences](#) on page 14-56
Refer to this section for information about the Internal DMA Controller Reception Sequences.

Internal DMA Controller Transmission Sequences

To use the internal DMA controller to transmit data, perform the following steps:

1. The host sets up the Descriptor fields (DES0—DES3) for transmission and sets the OWN bit (DES0[31]) to 1. The host also loads the data buffer in system memory with the data to be written to the SD card.[†]
2. The host writes the appropriate write data command (SD/SDIO WRITE_BLOCK or WRITE_MULTIPLE_BLOCK) to the `cmd` register. The internal DMA controller determines that a write data transfer needs to be performed.[†]
3. The host sets the required transmit threshold level in the `tx_wmark` field in the `fifoth` register.[†]
4. The internal DMA controller engine fetches the descriptor and checks the OWN bit. If the OWN bit is set to 0, the host owns the descriptor. In this case, the internal DMA controller enters the suspend state and asserts the Descriptor Unable interrupt. The host then needs to set the descriptor OWN bit to 1 and release the DMA controller by writing any value to the `pldmnd` register.[†]
5. The host must write the descriptor base address to the `dbaddr` register.[†]
6. The internal DMA controller waits for the Command Done (CD) bit in the `rintsts` register to be set to 1, with no errors from the BIU. This condition indicates that a transfer can be done.[†]
7. The internal DMA controller engine waits for a DMA interface request from BIU. The BIU divides each transfer into smaller chunks. Each chunk is an internal request to the DMA. This request is generated based on the transmit threshold value.[†]
8. The internal DMA controller fetches the transmit data from the data buffer in the system memory and transfers the data to the FIFO buffer in preparation for transmission to the card.[†]
9. When data spans across multiple descriptors, the internal DMA controller fetches the next descriptor and continues with its operation with the next descriptor. The Last Descriptor bit in the descriptor DES0 field indicates whether the data spans multiple descriptors or not.[†]
10. When data transmission is complete, status information is updated in the `idsts` register by setting the `ti` bit to 1, if enabled. Also, the OWN bit is set to 0 by the DMA controller by updating the DES0 field of the descriptor.[†]

Internal DMA Controller Reception Sequences

To use the internal DMA controller to receive data, perform the following steps:

1. The host sets up the descriptor fields (DES0—DES3) for reception, sets the OWN (DES0 [31]) to 1.[†]
2. The host writes the read data command to the `cmd` register in BIU. The internal DMA controller determines that a read data transfer needs to be performed.[†]
3. The host sets the required receive threshold level in the `rx_wmark` field in the `fifoth` register.[†]
4. The internal DMA controller engine fetches the descriptor and checks the OWN bit. If the OWN bit is set to 0, the host owns the descriptor. In this case, the internal DMA controller enters suspend state and asserts the Descriptor Unable interrupt. The host then needs to set the descriptor OWN bit to 1 and release the DMA controller by writing any value to the `pldmnd` register.[†]
5. The host must write the descriptor base address to the `dbaddr` register.[†]
6. The internal DMA controller waits for the CD bit in the `rintsts` register to be set to 1, with no errors from the BIU. This condition indicates that a transfer can be done.[†]
7. The internal DMA controller engine waits for a DMA interface request from the BIU. The BIU divides each transfer into smaller chunks. Each chunk is an internal request to the DMA. This request is generated based on the receive threshold value.[†]

8. The internal DMA controller fetches the data from the FIFO buffer and transfers the data to system memory.[†]
9. When data spans across multiple descriptors, the internal DMA controller fetches the next descriptor and continues with its operation with the next descriptor. The Last Descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.[†]
10. When data reception is complete, status information is updated in the `idsts` register by setting the `ri` bit to 1, if enabled. Also, the OWN bit is set to 0 by the DMA controller by updating the `DES0` field of the descriptor.[†]

Commands for SDIO Card Devices

This section describes the commands to temporarily halt the transfers between the controller and SDIO card device.

Suspend and Resume Sequence

For SDIO cards, a data transfer between an I/O function and the controller can be temporarily halted using the SUSPEND command. This capability might be required to perform a high-priority data transfer with another function. When desired, the suspended data transfer can be resumed using the RESUME command.[†]

The SUSPEND and RESUME operations are implemented by writing to the appropriate bits in the CCCR (Function 0) of the SDIO card. To read from or write to the CCCR, use the controller's IO_RW_DIRECT command.[†]

Suspend

To suspend data transfer, perform the following steps:[†]

1. Check if the SDIO card supports the SUSPEND/RESUME protocol. This can be done through the SBS bit in the CCCR at offset 0x08 of the card.[†]
2. Check if the data transfer for the required function number is in process. The function number that is currently active is reflected in the function select bits (FSx) of the CCCR, bits 3:0 at offset 0x0D of the card.[†]

Note: If the bus status bit (BS), bit 0 at address 0xC, is 1, only the function number given by the FSx bits is valid.[†]

3. To suspend the transfer, set the bus release bit (BR), bit 2 at address 0xC, to 1.[†]
4. Poll the BR and BS bits of the CCCR at offset 0x0C of the card until they are set to 0. The BS bit is 1 when the currently-selected function is using the data bus. The BR bit remains 1 until the bus release is complete. When the BR and BS bits are 0, the data transfer from the selected function is suspended.[†]
5. During a read-data transfer, the controller can be waiting for the data from the card. If the data transfer is a read from a card, the controller must be informed after the successful completion of the SUSPEND command. The controller then resets the data state machine and comes out of the wait state. To accomplish this, set the abort read data bit (`abort_read_data`) in the `ctrl` register to 1.[†]
6. Wait for data completion, by polling until the `dto` bit is set to 1 in the `rintsts` register. To determine the number of pending bytes to transfer, read the transferred CIU card byte count (`tcbcnt`) register of the controller. Subtract this value from the total transfer size. You use this number to resume the transfer properly.[†]

Resume

To resume the data transfer, perform the following steps:[†]

1. Check that the card is not in a transfer state, which confirms that the bus is free for data transfer.[†]
2. If the card is in a disconnect state, select it using the SD/SDIO SELECT/DESELECT_CARD command. The card status can be retrieved in response to an IO_RW_DIRECT or IO_RW_EXTENDED command.[†]
3. Check that a function to be resumed is ready for data transfer. Determine this state by reading the corresponding RF<n> flag in CCCR at offset 0x0F of the card. If RF<n> = 1, the function is ready for data transfer.[†]

Note: For detailed information about the RF<n> flags, refer to SDIO Simplified Specification Version 2.00, available on the SD Association website.[†]

4. To resume transfer, use the IO_RW_DIRECT command to write the function number at the FSx bits in the CCCR, bits 3:0 at offset 0x0D of the card. Form the command argument for the IO_RW_DIRECT command and write it to the cmdarg register. Bit values are listed in the following table.[†]

Table 14-27: cmdarg Bit Values for RESUME Command[†]

Bits	Content	Value
31	R/W flag	1
30:28	Function number	0, for CCCR access
27	RAW flag	1, read after write
26	Don't care	-
25:9	Register address	0x0D
8	Don't care	-
7:0	Write data	Function number that is to be resumed

5. Write the block size value to the blksize register. Data is transferred in units of this block size.[†]
6. Write the byte count value to the bytcnt register. Specify the total size of the data that is the remaining bytes to be transferred. It is the responsibility of the software to handle the data.[†]

To determine the number of pending bytes to transfer, read the transferred CIU card byte count register (tcbycnt). Subtract this value from the total transfer size to calculate the number of remaining bytes to transfer.[†]

7. Write to the cmd register similar to a block transfer operation. When the cmd register is written, the command is sent and the function resumes data transfer. For more information, refer to *Single-Block or Multiple-Block Read* and *Single-Block or Multiple-Block Write*.[†]
8. Read the resume data flag (DF) of the SDIO card device. Interpret the DF flag as follows:[†]

- DF=1—The function has data for the transfer and begins a data transfer as soon as the function or memory is resumed.[†]
- DF=0—The function has no data for the transfer. If the data transfer is a read, the controller waits for data. After the data timeout period, it issues a data timeout error.[†]

Refer to this section for more information about writing to the `cmd` register.

Read-Wait Sequence

`Read_wait` is used with SDIO cards only. It temporarily stalls the data transfer, either from functions or memory, and allows the host to send commands to any function within the SDIO card device. The host can stall this transfer for as long as required. The controller provides the facility to signal this stall transfer to the card.[†]

Signalling a Stall

To signal the stall, perform the following steps:[†]

1. Check if the card supports the `read_wait` facility by reading the SDIO card's SRW bit, bit 2 at offset 0x8 in the `CCCR`.[†]
2. If this bit is 1, all functions in the card support the `read_wait` facility. Use the SD/SDIO `IO_RW_DIRECT` command to read this bit.[†]
3. If the card supports the `read_wait` signal, assert it by setting the read wait bit (`read_wait`) in the `ctrl` register to 1.[†]
4. Reset the `read_wait` bit to 0 in the `ctrl` register.[†]

CE-ATA Data Transfer Commands

This section describes CE-ATA data transfer commands.

Related Information

[Data Transfer Commands](#) on page 14-46

Refer to this section for information about the basic settings and interrupts generated for different conditions.

Reset and Card Device Discovery Overview

Before starting any CE-ATA operations, the host must perform a MMC reset and initialization procedure. The host and card device must negotiate the MMC transfer (MMC TRAN) state before the card enters the MMC TRAN state.[†]

The host must follow the existing MMC discovery procedure to negotiate the MMC TRAN state. After completing normal MMC reset and initialization procedures, the host must query the initial ATA task file values using the `RW_REG` or `CMD39` command.[†]

By default, the MMC block size is 512 bytes—indicated by bits 1:0 of the `srcControl` register inside the CE-ATA card device. The host can negotiate the use of a 1 KB or 4 KB MMC block sizes. The card indicates MMC block sizes that it can support through the `srcCapabilities` register in the MMC; the host

reads this register to negotiate the MMC block size. Negotiation is complete when the host controller writes the MMC block size into the `srcControl` register bits 1:0 of the card.[†]

Related Information

www.jedec.org

For information about the (MMC TRAN) state, MMC reset and initialization, refer to JEDEC Standard No. 84-A441, available on the JEDEC website.

ATA Task File Transfer Overview

ATA task file registers are mapped to addresses 0x00h through 0x10h in the MMC register space. The `RW_REG` command is used to issue the ATA command, and the ATA task file is transmitted in a single `RW_REG` MMC command sequence.[†]

The host software stack must write the task file image to the FIFO buffer before setting the `cmdarg` and `cmd` registers in the controller. The host processor then writes the address and byte count to the `cmdarg` register before setting the `cmd` register bits.[†]

For the `RW_REG` command, there is no CCS from the CE-ATA card device.[†]

ATA Task File Transfer Using the `RW_MULTIPLE_REGISTER (RW_REG)` Command

This command involves data transfer between the CE-ATA card device and the controller. To send a data command, the controller needs a command argument, total data size, and block size. Software receives or sends data through the FIFO buffer.[†]

Implementing ATA Task File Transfer

To implement an ATA task file transfer (read or write), perform the following steps:[†]

1. Write the data size in bytes to the `bytcnt` register. `bytcnt` must equal the block size, because the controller expects a single block transfer.[†]
2. Write the block size in bytes to the `blksiz` register.[†]
3. Write the `cmdarg` register with the beginning register address.[†]

You must set the `cmdarg`, `cmd`, `blksiz`, and `bytcnt` registers according to the tables in *Register Settings for ATA Task File Transfer*.[†]

Related Information

[Register Settings for ATA Task File Transfer](#) on page 14-60

Refer to this table for information on how to set these registers.

Register Settings for ATA Task File Transfer

Table 14-28: `cmdarg` Register Settings for ATA Task File Transfer[†]

Bit	Value	Comment
31	1 or 0	Set to 0 for read operation or set to 1 for write operation
30:24	0	Reserved (bits set to 0 by host processor)
23:18	0	Starting register address for read or write (DWORD aligned)

Bit	Value	Comment
17:16	0	Register address (DWORD aligned)
15:8	0	Reserved (bits set to 0 by host processor)
7:2	16	Number of bytes to read or write (integral number of DWORD)
1:0	0	Byte count in integral number of DWORD

Table 14-29: cmd Register Settings for ATA Task File Transfer[†]

Bit	Value	Comment
start_cmd	1	
ccs_expected	0	CCS is not expected
read_ceata_device	0 or 1	Set to 1 if RW_BLK or RW_REG read
update_clk_regs_only	0	No clock parameters update command
card_num	0	
send_initialization	0	No initialization sequence
stop_abort_cmd	0	
send_auto_stop	0	
transfer_mode	0	Block transfer mode. Block size and byte count must match number of bytes to read or write
read_write	1 or 0	1 for write and 0 for read
data_expected	1	Data is expected
response_length	0	
response_expect	1	
cmd_index	Command index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).
wait_prvdata_complete	1	<ul style="list-style-type: none"> 0 for send command immediately 1 for send command after previous DTO interrupt

Bit	Value	Comment
check_response_crc	1	<ul style="list-style-type: none"> 0 for not checking response CRC 1 for checking response CRC

Table 14-30: blksiz Register Settings for ATA Task File Transfer[†]

Bit	Value	Comment
31:16	0	Reserved bits set to 0
15:0 (block_size)	16	For accessing entire task file (16, 8-bit registers). Block size of 16 bytes

Table 14-31: bytcnt Register Settings for ATA Task File Transfer

Bit	Value	Comment
31:0	16	For accessing entire task file (16, 8-bit registers). Byte count value of 16 is used with the block size set to 16.

ATA Payload Transfer Using the RW_MULTIPLE_BLOCK (RW_BLK) Command

This command involves data transfer between the CE-ATA card device and the controller. To send a data command, the controller needs a command argument, total data size, and block size. Software receives or sends data through the FIFO buffer. [†]

Implementing ATA Payload Transfer

To implement an ATA payload transfer (read or write), perform the following steps:[†]

1. Write the data size in bytes to the `bytcnt` register.[†]
2. Write the block size in bytes to the `blksiz` register. The controller expects a single/multiple block transfer.[†]
3. Write to the `cmdarg` register to indicate the data unit count.[†]

Register Settings for ATA Payload Transfer

You must set the `cmdarg`, `cmd`, `blksiz`, and `bytcnt` registers according to the following tables.[†]

Table 14-32: cmdarg Register Settings for ATA Payload Transfer[†]

Bits	Value	Comment
31	1 or 0	Set to 0 for read operation or set to 1 for write operation
30:24	0	Reserved (bits set to 0 by host processor)
23:16	0	Reserved (bits set to 0 by host processor)
15:8	Data count	Data Count Unit [15:8]

Bits	Value	Comment
7:0	Data count	Data Count Unit [7:0]

Table 14-33: cmd Register Settings for ATA Payload Transfer[†]

Bits	Value	Comment
start_cmd	1	-
ccs_expected	1	CCS is expected. Set to 1 for the RW_BLK command if interrupts are enabled in CE-ATA card device (the nIEN bit is set to 0 in the ATA control register)
read_ceata_device	0 or 1	Set to 1 for a RW_BLK or RW_REG read command
update_clk_regs_only	0	No clock parameters update command
card_num	0	-
send_initialization	0	No initialization sequence
stop_abort_cmd	0	-
send_auto_stop	0	-
transfer_mode	0	Block transfer mode. Byte count must be integer multiple of 4kB. Block size can be 512, 1k or 4k bytes
read_write	1 or 0	1 for write and 0 for read
data_expected	1	Data is expected
response_length	0	-
response_expect	1	-
cmd_index	Command index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).
wait_prvdata_complete	1	<ul style="list-style-type: none"> 0 for send command immediately 1 for send command after previous DTO interrupt

Bits	Value	Comment
check_response_crc	1	<ul style="list-style-type: none"> 0 for not checking response CRC 1 for checking response CRC

Table 14-34: blksiz Register Settings for ATA Payload Transfer[†]

Bits	Value	Comment
31:16	0	Reserved bits set to 0
15:0 (block_size)	512, 1024 or 4096	MMC block size can be 512, 1024 or 4096 bytes as negotiated by host

Table 14-35: bytcnt Register Settings for ATA Payload Transfer

Bits	Value	Comment
31:0	$\langle n \rangle * \text{block_size}$	<p>Byte count must be an integer multiple of the block size. For ATA media access commands, byte count must be a multiple of 4 KB.</p> <p>($\langle n \rangle * \text{block_size} = \langle x \rangle * 4 \text{ KB}$, where $\langle n \rangle$ and $\langle x \rangle$ are integers)</p>

CE-ATA CCS

This section describes disabling the CCS, recovery after CCS timeout, and recovery after I/O read transmission delay (N_{ACIO}) timeout. [†]

Disabling the CCS

While waiting for the CCS for an outstanding RW_BLK command, the host can disable the CCS by sending a CCSD command:[†]

- Send a CCSD command—the controller sends the CCSD command to the CE-ATA card device if the `send_ccsd` bit is set to 1 in the `ctrl` register of the controller. This bit can be set only after a response is received for the RW_BLK command.[†]
- Send an internal stop command—send an internally-generated SD/SDIO STOP_TRANSMISSION (CMD12) command after sending the CCSD pattern. If the `send_auto_stop_ccsd` bit of the `ctrl` register is also set to 1 when the controller is set to send the CCSD pattern, the controller sends the internally-generated STOP command to the `CMD` pin. After sending the STOP command, the controller sets the `acd` bit in the `rintsts` register to 1.[†]

Recovery after CCS Timeout

If a timeout occurs while waiting for the CCS, the host needs to send the CCSD command followed by a STOP command to abort the pending ATA command. The host can set up the controller to send an internally-generated STOP command after sending the CCSD pattern:[†]

- Send CCSD command—set the `send_ccsd` bit in the `ctrl` register to 1.[†]
- Send external STOP command—terminate the data transfer between the CE-ATA card device and the controller. For more information about sending the STOP command, refer to *Transfer Stop and Abort Commands*.[†]
- Send internal STOP command—set the `send_auto_stop_ccsd` bit in the `ctrl` register to 1, which tells the controller to send the internally-generated STOP command. After sending the STOP command, the controller sets the `acd` bit in the `rintsts` register to 1. The `send_auto_stop_ccsd` bit must be set to 1 along with setting the `send_ccsd` bit.[†]

Related Information

[Transfer Stop and Abort Commands](#) on page 14-53

Refer to this section for more information about sending the STOP command.

Recovery after I/O Read Transmission Delay (N_{ACIO}) Timeout

If the I/O read transmission delay (N_{ACIO}) timeout occurs for the CE-ATA card device, perform one of the following steps to recover from the timeout:[†]

- If the CCS is expected from the CE-ATA card device (that is, the `ccs_expected` bit is set to 1 in the `cmd` register), follow the steps in *Recovery after CCS Timeout*.[†]
- If the CCS is not expected from the CE-ATA card device, perform the following steps:[†]
 1. Send an external STOP command.[†]
 2. Terminate the data transfer between the controller and CE-ATA card device.[†]

Related Information

[Recovery after CCS Timeout](#) on page 14-64

For more information about what steps to take if the CCS is expected from the CE-ATA card device.

Reduced ATA Command Set

It is necessary for the CE-ATA card device to support the reduced ATA command subset. This section describes the reduced command set.[†]

The IDENTIFY DEVICE Command

The IDENTIFY DEVICE command returns a 512-byte data structure to the host that describes device-specific information and capabilities. The host issues the IDENTIFY DEVICE command only if the MMC block size is set to 512 bytes. Any other MMC block size has indeterminate results.[†]

The host issues a `RW_REG` command for the ATA command, and the data is retrieved with the `RW_BLK` command.[†]

The host controller uses the following settings while sending a `RW_REG` command for the IDENTIFY DEVICE ATA command. The following list shows the primary bit settings:[†]

- `cmd` register setting: `data_expected` bit set to 0[†]
- `cmdarg` register settings:[†]
 - Bit [31] set to 0[†]
 - Bits [7:2] set to 128[†]
 - All other bits set to 0[†]
- Task file settings:[†]
 - Command field of the ATA task file set to 0xEC[†]
 - Reserved fields of the task file set to 0[†]
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 16[†]

The host controller uses the following settings for data retrieval (RW_BLK command):[†]

- cmd register settings:[†]
 - ccs_expected set to 1[†]
 - data_expected set to 1[†]
- cmdarg register settings:[†]
 - Bit [31] set to 0 (read operation) [†]
 - Bits [15:0] set to 1 (data unit count = 1)[†]
 - All other bits set to 0[†]
- bytcnt register and block_size field of the blksize register: set to 512[†]

The READ DMA EXT Command

The READ DMA EXT command reads a number of logical blocks of data from the card device using the Data-In data transfer protocol. The host uses a RW_REG command to issue the ATA command and the RW_BLK command for the data transfer.[†]

The WRITE DMA EXT Command

The WRITE DMA EXT command writes a number of logical blocks of data to the card device using the Data-Out data transfer protocol. The host uses a RW_REG command to issue the ATA command and the RW_BLK command for the data transfer.[†]

The STANDBY IMMEDIATE Command

This ATA command causes the card device to immediately enter the most aggressive power management mode that still retains internal device context. No data transfer (RW_BLK) is expected for this command.[†]

For card devices that do not provide a power savings mode, the STANDBY IMMEDIATE command returns a successful status indication. The host issues a RW_REG command for the ATA command, and the status is retrieved with the SD/SDIO CMD39 or RW_REG command. Only the status field of the ATA task file contains the success status; there is no error status.[†]

The host controller uses the following settings while sending the RW_REG command for the STANDBY IMMEDIATE ATA command:[†]

- cmd register setting: data_expected bit set to 0[†]
- cmdarg register settings:[†]
 - Bit [31] set to 1 [†]
 - Bits [7:2] set to 4 [†]
 - All other bits set to 0 [†]
- Task file settings:[†]
 - Command field of the ATA task file set to 0xE0[†]
 - Reserved fields of the task file set to 0[†]
- bytcnt register and block_size field of the blksize register: set to 16 [†]

The FLUSH CACHE EXT Command

For card devices that buffer/cache written data, the FLUSH CACHE EXT command ensures that buffered data is written to the card media. For cards that do not buffer written data, the FLUSH CACHE EXT command returns a success status. No data transfer (RW_BLK) is expected for this ATA command.[†]

The host issues a RW_REG command for the ATA command, and the status is retrieved with the SD/SDIO CMD39 or RW_REG command. There can be error status for this ATA command, in which case fields other than the status field of the ATA task file are valid.[†]

The host controller uses the following settings while sending the RW_REG command for the STANDBY IMMEDIATE ATA command:[†]

- cmd register setting: data_expected bit set to 0[†]
- cmdarg register settings: [†]
 - Bit [31] set to 1[†]
 - Bits [7:2] set to 4[†]
 - All other bits set to 0[†]
- Task file settings: [†]
 - Command field of the ATA task file set to 0xEA[†]
 - Reserved fields of the task file set to 0[†]
- bytcnt register and block_size field of the blksize register: set to 16[†]

Card Read Threshold

When an application needs to perform a single or multiple block read command, the application must set the cardthrcnt1 register with the appropriate card read threshold size in the card read threshold field (cardrdthreshold) and set the cardrdthren bit to 1. This additional information specified in the controller ensures that the controller sends a read command only if there is space equal to the card read threshold available in the RX FIFO buffer. This in turn ensures that the card clock is not stopped in the middle a block of data being transmitted from the card. Set the card read threshold to the block size of the transfer to guarantee there is a minimum of one block size of space in the RX FIFO buffer before the controller enables the card clock.[†]

The card read threshold is required when the round trip delay is greater than half of sdmmc_clk_divided.[†]

Table 14-36: Card Read Threshold Guidelines[†]

Bus Speed Modes	Round Trip Delay (Delay_R) ⁽⁴⁴⁾	Is Stopping of Card Clock Allowed?	Card Read Threshold Required?
SDR25	Delay_R > 0.5 * (sdmmc_clk/4)	No	Yes
	Delay_R < 0.5 * (sdmmc_clk/4)	Yes	No
SDR12	Delay_R > 0.5 * (sdmmc_clk/4)	No	Yes
	Delay_R < 0.5 * (sdmmc_clk/4)	Yes	No

Related Information

http://www.altera.com/literature/hb/cyclone-v/cv_51002.pdf

⁽⁴⁴⁾ Delay_R = Delay_O + tODLY + Delay_I[†]

Where: [†]

Delay_O = sdmmc_clk to sdmmc_cclk_out delay (including I/O pin delay)[†]

Delay_I = Input I/O pin delay + routing delay to the input register[†]

tODLY = sdmmc_cclk_out to card output delay (varies across card manufactures and speed modes)[†]

For the delay numbers needed for above calculation, refer to Arria 10 Datasheet.[†]

Recommended Usage Guidelines for Card Read Threshold

1. The `cardthrc1` register must be set before setting the `cmd` register for a data read command.[†]
2. The `cardthrc1` register must not be set while a data transfer command is in progress.[†]
3. The `cardrdthreshold` field of the `cardthrc1` register must be set to at the least the block size of a single or multiblock transfer. A `cardrdthreshold` field setting greater than or equal to the block size of the read transfer ensures that the card clock does not stop in the middle of a block of data.[†]
4. If the round trip delay is greater than half of the card clock period, card read threshold must be enabled and the card threshold must be set as per guideline 3 to guarantee that the card clock does not stop in the middle of a block of data.[†]
5. If the `cardrdthreshold` field is set to less than the block size of the transfer, the host must ensure that the receive FIFO buffer never overflows during the read transfer. Overflow can cause the card clock from the controller to stop. The controller is not able to guarantee that the card clock does not stop during a read transfer.[†]

Note: If the `cardrdthreshold` field of the `cardthrc1` register, and the `rx_wmark` and `dw_dma_multiple_transaction_size` fields of the `fifoth` register are set incorrectly, the card clock might stop indefinitely, with no interrupts generated by the controller.[†]

Card Read Threshold Programming Sequence

Most cards, such as SDHC or SDXC, support block sizes that are either specified in the card or are fixed to 512 bytes. For SDIO, MMC, and standard capacity SD cards that support partial block read (`READ_BL_PARTIAL` set to 1 in the CSD register of the card device), the block size is variable and can be chosen by the application.[†]

To use the card read threshold feature effectively and to guarantee that the card clock does not stop because of a FIFO Full condition in the middle of a block of data being read from the card, follow these steps:[†]

1. Choose a block size that is a multiple of four bytes.[†]
2. Enable card read threshold feature. The card read threshold can be enabled only if the block size for the given transfer is less than or equal to the total depth of the FIFO buffer:[†]

$$(\text{block size} / 4) \leq 1024^{\dagger}$$
3. Choose the card read threshold value:[†]
 - If $(\text{block size} / 4) \geq 512$, choose `cardrdthreshold` such that:[†]
 - $\text{cardrdthreshold} \leq (\text{block size} / 4)$ in bytes[†]
 - If $(\text{block size} / 4) < 512$, choose `cardrdthreshold` such that:[†]
 - $\text{cardrdthreshold} = (\text{block size} / 4)$ in bytes[†]
4. Set the `dw_dma_multiple_transaction_size` field in the `fifoth` register to the number of transfers that make up a DMA transaction. For example, `size = 1` means 4 bytes are moved. The possible values for the size are 1, 4, 8, 16, 32, 64, 128, and 256 transfers. Select the size so that the value $(\text{block size} / 4)$ is evenly divided by the size.[†]
5. Set the `rx_wmark` field in the `fifoth` register to the `size - 1`.[†]

For example, if your block size is 512 bytes, legal values of `dw_dma_multiple_transaction_size` and `rx_wmark` are listed in the following table.

Table 14-37: Legal Values of dw_dma_multiple_transaction_size and rx_wmark for Block Size = 512[†]

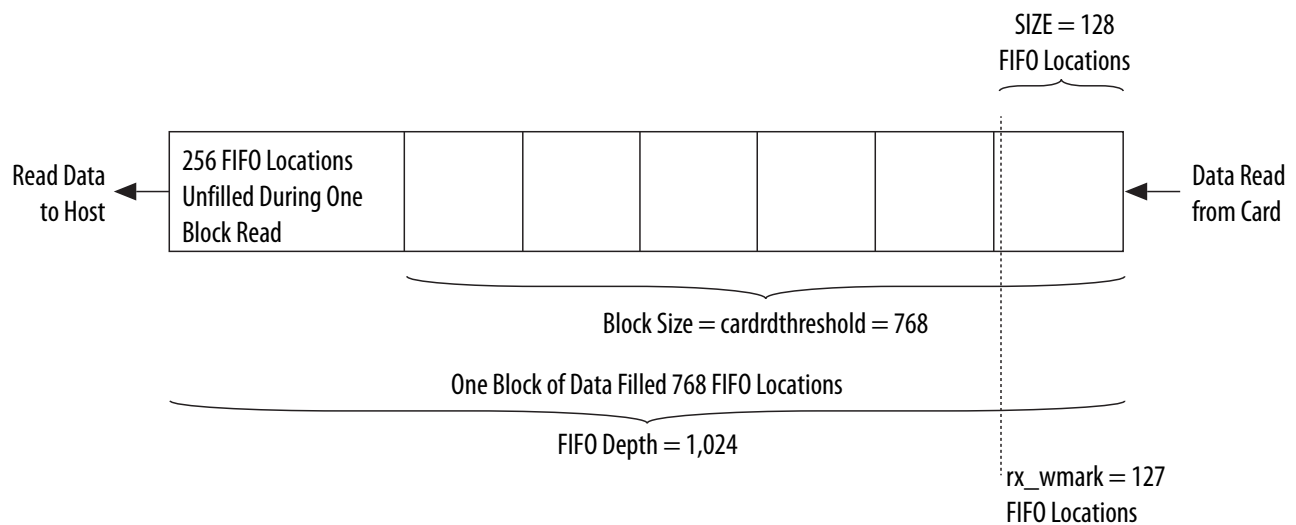

Block Size	dw_dma_multiple_transaction_size	rx_wmark
512	1	0
512	4	3
512	8	7
512	16	15
512	32	31
512	64	63
512	128	127

Card Read Threshold Programming Examples

This section shows examples of how to program the card read threshold.[†]

- Choose a block size that is a multiple of 4 (the number of bytes per FIFO location), and less than 4096 (1024 FIFO locations). For example, a block size of 3072 bytes is legal, because $3072 / 4 = 768$ FIFO locations.[†]
- For DMA mode, choose the size so that block size is a multiple of the size. For example size = 128, where $\text{block size} \% \text{size} = 0$.[†]
- Set the rx_wmark field = size - 1. For example, the rx_wmark field = $128 - 1 = 127$.[†]
- Because $\text{block size} > \frac{1}{2} \text{FifoDepth}$, set the cardrdthreshold field to the block size. For example, the cardrdthreshold field = 3072 bytes.[†]

Figure 14-13: FIFO Buffer content when Card Read Threshold is set to 768[†]

Interrupt and Error Handling

This section describes how to use interrupts to handle errors. On power-on or reset, interrupts are disabled (the `int_enable` bit in the `ctrl` register is set to 0), and all the interrupts are masked (the `intmask` register default is 0). The controller error handling includes the following types of errors:

- Response and data timeout errors—For response time-outs, the host software can retry the command. For data time-outs, the controller has not received the data start bit from the card, so software can either retry the whole data transfer again or retry from a specified block onwards. By reading the contents of the `tcbscnt` register later, the software can decide how many bytes remain to be copied (read).[†]
- Response errors—Set to 1 when an error is received during response reception. If the response received is invalid, the software can retry the command.[†]
- Data errors—Set to 1 when a data receive error occurs. Examples of data receive errors:[†]
 - Data CRC[†]
 - Start bit not found[†]
 - End bit not found[†]

These errors can occur on any block. On receipt of an error, the software can issue an SD/SDIO STOP or SEND_IF_COND command, and retry the command for either the whole data or partial data.[†]

- Hardware locked error—Set to 1 when the controller cannot load a command issued by software. When software sets the `start_cmd` bit in the `cmd` register to 1, the controller tries to load the command. If the command buffer already contains a command, this error is raised, and the new command is discarded, requiring the software to reload the command.[†]
- FIFO buffer underrun/overflow error—If the FIFO buffer is full and software tries to write data to the FIFO buffer, an overflow error is set. Conversely, if the FIFO buffer is empty and the software tries to read data from the FIFO buffer, an underrun error is set. Before reading or writing data in the FIFO buffer, the software must read the FIFO buffer empty bit (`fifo_empty`) or FIFO buffer full bit (`fifo_full`) in the `status` register.[†]
- Data starvation by host timeout—This condition occurs when software does not service the FIFO buffer fast enough to keep up with the controller. Under this condition and when a read transfer is in process, the software must read data from the FIFO buffer, which creates space for further data reception. When a transmit operation is in process, the software must write data to fill the FIFO buffer so that the controller can write the data to the card.[†]
- CE-ATA errors[†]
- CRC error on command—If a CRC error is detected for a command, the CE-ATA card device does not send a response, and a response timeout is expected from the controller. The ATA layer is notified that an MMC transport layer error occurred.

- CRC error on command—If a CRC error is detected for a command, the CE-ATA card device does not send a response, and a response timeout is expected from the controller. The ATA layer is notified that an MMC transport layer error occurred.[†]
- Write operation—Any MMC transport layer error known to the card device causes an outstanding ATA command to be terminated. The ERR bits are set in the ATA status registers and the appropriate error code is sent to the Error Register (Error) on the ATA card device.[†]

If the device interrupt bit of the CE-ATA card (the nIEN bit in the ATA control register) is set to 0, the CCS is sent to the host.[†]

If the device interrupt bit is set to 1, the card device completes the entire data unit count if the host controller does not abort the ongoing transfer.[†]

Note: During a multiple-block data transfer, if a negative CRC status is received from the card device, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register to 1. It then continues further data transmission until all the bytes are transmitted.[†]

- Read operation—If MMC transport layer errors are detected by the host controller, the host completes the ATA command with an error status. The host controller can issue a CCSD command followed by a STOP_TRANSMISSION (CMD12) command to abort the read transfer. The host can also transfer the entire data unit count bytes without aborting the data transfer.[†]

Booting Operation for eMMC and MMC

This section describes how to set up the controller for eMMC and MMC boot operation.

Note: The BootROM and initial software do not use the boot partitions that are in the MMC card. This means that there is no boot partition support of the SD/MMC controller.

Boot Operation by Holding Down the CMD Line

The controller can boot from MMC4.3, MMC4.4, and MMC4.41 cards by holding down the CMD line.

For information about this boot method, refer to the following specifications, available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

Related Information

www.jedec.org

For more information about this boot method, refer to the following JEDEC Standards available on the JEDEC website: No. 84-A441, No. 84-A44, and No. JESD84-A43.

Boot Operation for eMMC Card Device

The following figure illustrates the steps to perform the boot process for eMMC card devices. The detailed steps are described following the flow chart.

Figure 14-14: Flow for eMMC Boot Operation[†]

1. The software driver performs the following checks: [†]

- If the eMMC card device supports boot operation (the `BOOT_PARTITION_ENABLE` bit is set to 1 in the `EXT_CSD` register of the eMMC card).[†]
- The `BOOT_SIZE_MULT` and `BOOT_BUS_WIDTH` values in the `EXT_CSD` register, to be used during the boot process.[†]

2. The software sets the following bits: [†]

- Sets masks for interrupts, by setting the appropriate bits to 0 in the `intmask` register.[†]
- Sets the global `int_enable` bit of the `ctrl` register to 1. Other bits in the `ctrl` register must be set to 0.[†]

Note: Altera recommends that you write `0xFFFFFFFF` to the `rintsts` and `idsts` registers to clear any pending interrupts before setting the `int_enable` bit. For internal DMA controller mode, the software driver needs to unmask all the relevant fields in the `idinten` register.[†]

3. If the software driver needs to use the internal DMA controller to transfer the boot data received, it must perform the following steps: [†]

- Set up the descriptors as described in *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences*.[†]
 - Set the `use_internal_dmac` bit of the `ctrl` register to 1.[†]
4. Set the card device frequency to 400 kHz using the `clkdiv` registers. For more information, refer to *Clock Setup*.[†]
 5. Set the `data_timeout` field of the `tmout` register equal to the card device total access time, N_{AC} .[†]
 6. Set the `blksiz` register to 0x200 (512 bytes).[†]
 7. Set the `bytcnt` register to a multiple of 128 KB, as indicated by the `BOOT_SIZE_MULT` value in the card device.[†]
 8. Set the `rx_wmark` field in the `fifoth` register. Typically, the threshold value can be set to 512, which is half the FIFO buffer depth.[†]
 9. Set the following fields in the `cmd` register:[†]
 - Initiate the command by setting `start_cmd` = 1[†]
 - Enable boot (`enable_boot`) = 1[†]
 - Expect boot acknowledge (`expect_boot_ack`):[†]
 - If a start-acknowledge pattern is expected from the card device, set `expect_boot_ack` to 1.[†]
 - If a start-acknowledge pattern is not expected from the card device, set `expect_boot_ack` to 0.[†]
 - Card number (`card_number`) = 0[†]
 - `data_expected` = 1[†]
 - Reset the remainder of `cmd` register bits to 0[†]
 10. If no start-acknowledge pattern is expected from the card device (`expect_boot_ack` set to 0) proceed to [step 12](#).[†]
 11. This step handles the case where a start-acknowledge pattern is expected (`expect_boot_ack` was set to 1 in [step 9](#)).[†]
 - a. If the Boot ACK Received interrupt is not received from the controller within 50 ms of initiating the command ([step 9](#)), the software driver must set the following `cmd` register fields:[†]
 - `start_cmd` = 1[†]
 - Disable boot (`disable_boot`) = 1[†]
 - `card_number` = 0[†]
 - All other fields = 0[†]

The controller generates a Command Done interrupt after deasserting the `CMD` pin of the card interface.[†]

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:[†]

- The DMA descriptor is closed.[†]
 - The `ces` bit in the `idsts` register is set, indicating the Boot ACK Received timeout.[†]
 - The `ri` bit of the `idsts` register is not set.[†]
- b. If the Boot ACK Received interrupt is received, the software driver must clear this interrupt by writing 1 to the `ces` bit in the `idsts` register.[†]

Within 0.95 seconds of the Boot ACK Received interrupt, the Boot Data Start interrupt must be received from the controller. If this does not occur, the software driver must write the following `cmd` register fields:[†]

- `start_cmd` = 1[†]
- `disable_boot` = 1[†]
- `card_number` = 0[†]
- All other fields = 0[†]

The controller generates a Command Done interrupt after deasserting the `CMD` pin of the card interface.[†]

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:[†]

- The DMA descriptor is closed[†]
 - The `ces` bit in the `idsts` register is set, indicating Boot Data Start timeout[†]
 - The `ri` bit of the `idsts` register is not set[†]
- c. If the Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.[†]

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level set in the `rx_wmark` field of the `fifoth` register is reached.[†]

At the end of a successful boot data transfer from the card, the following interrupts are generated:[†]

- The `cmd` bit and `dto` bit in the `rintsts` register[†]
 - The `ri` bit in the `idsts` register, in internal DMA controller mode only[†]
- d. If an error occurs in the boot ACK pattern (0b010) or an EBE occurs:[†]
- The controller automatically aborts the boot process by pulling the `CMD` line high[†]
 - The controller generates a Command Done interrupt[†]
 - The controller does not generate a Boot ACK Received interrupt[†]
 - The application aborts the boot transfer[†]
- e. In internal DMA controller mode:[†]
- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. Software cannot reuse the descriptors until they are closed.[†]
 - If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.[†]
- f. If N_{AC} is violated between data block transfers, the `DRTO` interrupt is asserted. In addition, if there is an error associated with the start or end bit, the `SBE` or `EBE` interrupt is also generated.[†]

The boot operation for eMMC card devices is complete. Do not execute the remaining (**step 12**).[†]

12. This step handles the case where no start-acknowledge pattern is expected (`expect_boot_ack` was set to 0 in **step 9**).[†]

- a. If the Boot Data Start interrupt is not received from the controller within 1 second of initiating the command (**step 9**), the software driver must write the `cmd` register with the following fields:[†]
- `start_cmd` = 1[†]
 - `disable_boot` = 1[†]
 - `card_number` = 0[†]
 - All other fields = 0[†]

The controller generates a Command Done interrupt after deasserting the `CMD` line of the card. In internal DMA controller mode, the descriptor is closed and the `ces` bit in the `idsts` register is set to 1, indicating a Boot Data Start timeout.[†]

- b. If a Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver

can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached.†

At the end of a successful boot data transfer from the card, the following interrupts are generated:†

- The `cmd` bit and `dto` bit in the `rintsts` register†
 - The `ri` bit in the `idsts` register, in internal DMA controller mode only†
- c. In internal DMA controller mode:†
- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller.†
 - If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

The boot operation for eMMC card devices is complete.†

Boot Operation for Removable MMC4.3, MMC4.4 and MMC4.41 Cards

Removable MMC4.3, MMC4.4, and MMC4.41 Differences

Removable MMC4.3, MMC4.4, and MMC4.41 cards differ with respect to eMMC in that the controller is not aware whether these cards support the boot mode of operation when plugged in. Thus, the controller must: †

1. Discover these cards as it would discover MMC4.0/4.1/4.2 cards for the first time†
2. Know the card characteristics †
3. Decide whether to perform a boot operation or not†

Bootable Removable MMC4.3, MMC4.4 and MMC4.41 Cards

For removable MMC4.3, MMC4.4 and MMC4.41 cards, the software driver must perform the following steps:†

1. Discover the card as described in *Enumerated Card Stack*.†
2. Read the EXT_CSD register of the card and examine the following fields: †
 - `BOOT_PARTITION_ENABLE` †
 - `BOOT_SIZE_MULT`†
 - `BOOT_INFO` †
3. If necessary, the software can manipulate the boot information in the card. †

Note: For more information, refer to “Access to Boot Partition” in the following specifications available on the JEDEC website:

- JEDEC Standard No. 84-A441
 - JEDEC Standard No. 84-A44
 - JEDEC Standard No. JESD84-A43
4. If the host processor needs to perform a boot operation at the next power-up cycle, it can manipulate the EXT_CSD register contents by using a SWITCH_FUNC command. †
 5. After this step, the software driver must power down the card by writing to the `pwren` register. †
 6. From here on, use the same steps as in *Alternative Boot Operation for eMMC Card Devices*. †

Related Information

- [Enumerated Card Stack](#) on page 14-40
Refer to this section for more information on discovering removable MMC cards.
- <http://www.jedec.org>
- [Alternative Boot Operation for eMMC Card Devices](#) on page 14-76
Refer to this section for information about alternative boot operation steps.

Alternative Boot Operation

The alternative boot operation differs from the previous boot operation in that software uses the SD/SDIO GO_IDLE_STATE command to boot the card, rather than holding down the CMD line of the card. The alternative boot operation can be performed only if bit 0 in the BOOT_INFO register is set to 1. BOOT_INFO is located at offset 228 in the EXT_CSD registers. †

For detailed information about alternative boot operation, refer to the following specifications available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

Related Information

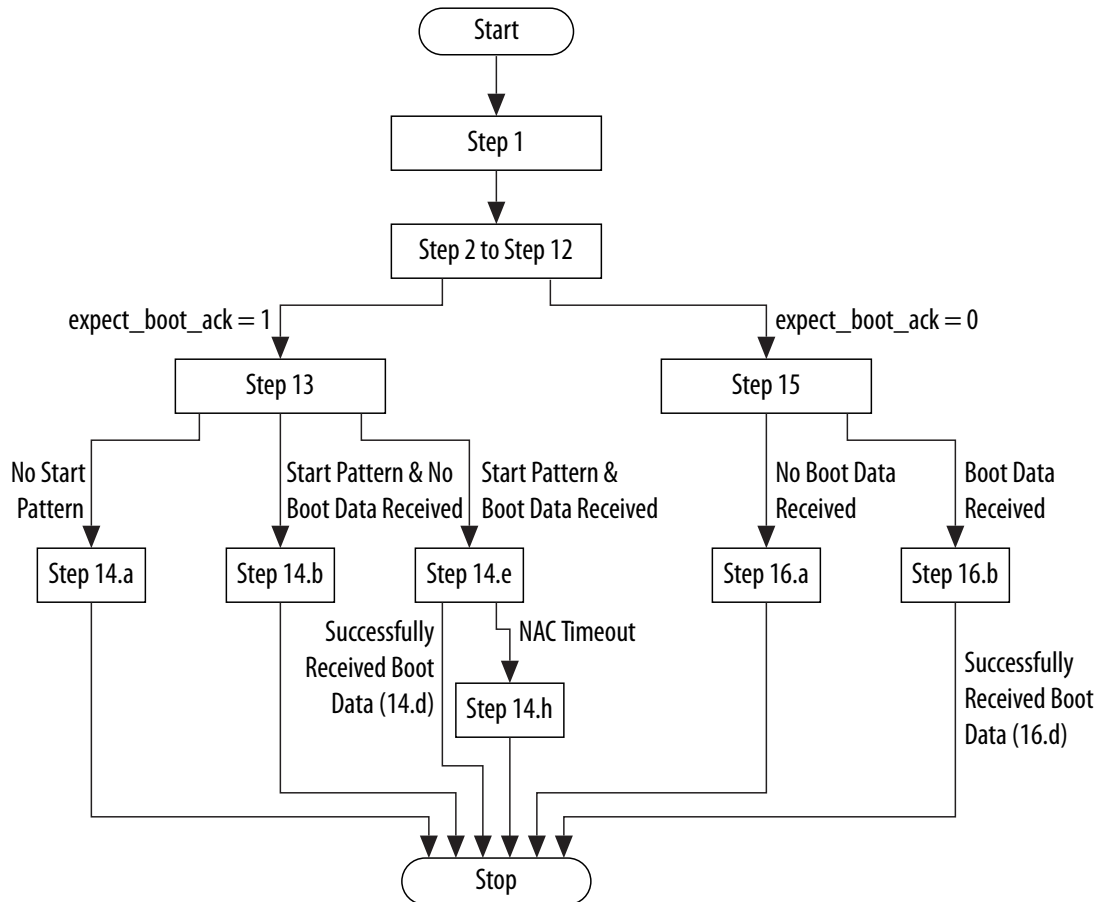

www.jedec.org

For more information about alternative boot operation, refer to the following JEDEC Standards available on the JEDEC website: No. 84-A441, No. 84-A44, and No. JESD84-A43.

Alternative Boot Operation for eMMC Card Devices

The following figure illustrates the sequence of steps required to perform the alternative boot operation for eMMC card devices. The detailed steps are described following the flow chart.

Figure 14-15: Flow for eMMC Alternative Boot Operation[†]

1. The software driver checks:[†]

- If the eMMC card device supports alternative boot operation (the BOOT_INFO bit is set to 1 in the eMMC card).[†]
- The BOOT_SIZE_MULT and BOOT_BUS_WIDTH values in the card device to use during the boot process.[†]

2. The software sets the following bits:[†]

- Sets masks for interrupts by resetting the appropriate bits to 0 in the `intmask` register.[†]
- Sets the `int_enable` bit of the `ctrl` register to 1. Other bits in the `ctrl` register must be set to 0.[†]

Note: Altera recommends writing 0xFFFFFFFF to the `rintsts` register and `idsts` register to clear any pending interrupts before setting the `int_enable` bit. For internal DMA controller mode, the software driver needs to unmask all the relevant fields in the `idinten` register.[†]

3. If the software driver needs to use the internal DMA controller to transfer the boot data received, it must perform the following actions:[†]

- Set up the descriptors as described in *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences*.[†]
- Set the use internal DMAC bit (`use_internal_dmac`) of the `ctrl` register to 1.[†]

4. Set the card device frequency to 400 kHz using the `clkdiv` registers. For more information, refer to *Clock Setup*. Ensure that the card clock is running.[†]

5. Wait for a time that ensures that at least 74 card clock cycles have occurred on the card interface.[†]
6. Set the `data_timeout` field of the `tmout` register equal to the card device total access time, N_{AC} .[†]
7. Set the `blksiz` register to 0x200 (512 bytes).[†]
8. Set the `bytcnt` register to multiples of 128K bytes, as indicated by the `BOOT_SIZE_MULT` value in the card device.[†]
9. Set the `rx_wmark` field in the `fifoth` register. Typically, the threshold value can be set to 512, which is half the FIFO buffer depth.[†]
10. Set the `cmdarg` register to 0xFFFFFFFFFA.[†]
11. Initiate the command, by setting the `cmd` register with the following fields:[†]
 - `start_cmd` = 1[†]
 - `enable_boot` = 1[†]
 - `expect_boot_ack`:[†]
 - If a start-acknowledge pattern is expected from the card device, set `expect_boot_ack` to 1.[†]
 - If a start-acknowledge pattern is not expected from the card device, set `expect_boot_ack` to 0.[†]
 - `card_number` = 0[†]
 - `data_expected` = 1[†]
 - `cmd_index` = 0[†]
 - Set the remainder of `cmd` register bits to 0.[†]
12. If no start-acknowledge pattern is expected from the card device (`expect_boot_ack` set to 0) jump to [step 15](#).[†]
13. Wait for the Command Done interrupt.[†]
14. This step handles the case where a start-acknowledge pattern is expected (`expect_boot_ack` was set to 1 in [step 11](#)).[†]
 - a. If the Boot ACK Received interrupt is not received from the controller within 50 ms of initiating the command ([step 11](#)), the start pattern was not received. The software driver must discontinue the boot process and start with normal discovery.[†]

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:[†]

 - The DMA descriptor is closed.[†]
 - The `ces` bit in the `idsts` register is set to 1, indicating the Boot ACK Received timeout.[†]
 - The `ri` bit of the `idsts` register is not set.[†]
 - b. If the Boot ACK Received interrupt is received, the software driver must clear this interrupt by writing 1 to it.[†]

Within 0.95 seconds of the Boot ACK Received interrupt, the Boot Data Start interrupt must be received from the controller. If this does not occur, the software driver must discontinue the boot process and start with normal discovery.[†]

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:[†]

 - The DMA descriptor is closed.[†]
 - The `ces` bit in the `idsts` register is set to 1, indicating Boot Data Start timeout.[†]
 - The `ri` bit of the `idsts` register is not set.[†]
 - c. If the Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.[†]

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached. †

- d. The software driver must terminate the boot process by instructing the controller to send the SD/SDIO `GO_IDLE_STATE` command: †
 - Reset the `cmdarg` register to 0. †
 - Set the `start_cmd` bit of the `cmd` register to 1, and all other bits to 0. †
- e. At the end of a successful boot data transfer from the card, the following interrupts are generated: †
 - The `cmd` bit and `dto` bit in the `rintsts` register †
 - The `ri` bit in the `idsts` register, in internal DMA controller mode only †
- f. If an error occurs in the boot ACK pattern (0b010) or an EBE occurs: †
 - The controller does not generate a Boot ACK Received interrupt. †
 - The controller detects Boot Data Start and generates a Boot Data Start interrupt. †
 - The controller continues to receive boot data. †
 - The application must abort the boot process after receiving a Boot Data Start interrupt. †
- g. In internal DMA controller mode: †
 - If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. †
 - If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory. †
- h. If N_{AC} is violated between data block transfers, a DRTO interrupt is asserted. Apart from this, if there is an error associated with the start or end bit, the SBE or EBE interrupt is also generated. †

The alternative boot operation for eMMC card devices is complete. Do not execute the remaining steps (15 and 16). †

15. Wait for the Command Done interrupt. †

16. This step handles the case where a start-acknowledge pattern is not expected (`expect_boot_ack` was set to 0 in [step 11](#)). †

- a. If the Boot Data Start interrupt is not received from the controller within 1 second of initiating the command ([step 11](#)), the software driver must discontinue the boot process and start with normal discovery. † In internal DMA controller mode: †
 - The DMA descriptor is closed. †
 - The `ces` bit in the `idsts` register is set to 1, indicating Boot Data Start timeout. †
 - The `ri` bit of the `idsts` register is not set. †
- b. If a Boot Data Start interrupt is received, the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register. †

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached. †

- c. The software driver must terminate the boot process by instructing the controller to send the SD/SDIO `GO_IDLE_STATE` (`CMD0`) command: †
 - Reset the `cmdarg` register to 0. †
 - Set the `start_cmd` bit in the `cmd` register to 1, and all other bits to 0. †
- d. At the end of a successful boot data transfer from the card, the following interrupts are generated: †

- The `cmd` bit and `dto` bit in the `rintsts` register[†]
 - The `ri` bit in the `idsts` register, in internal DMA controller mode only[†]
- e. In internal DMA controller mode:[†]
- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller.[†]
 - If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.[†]

The alternative boot operation for eMMC card devices is complete.[†]

Alternative Boot Operation for MMC4.3 Cards

Removable MMC4.3 Boot Mode Support

Removable MMC4.3 cards differ with respect to eMMC in that the controller is not aware whether these cards support the boot mode of operation. Thus, the controller must:[†]

1. Discover these cards as it would discover MMC4.0/4.1/4.2 cards for the first time[†]
2. Know the card characteristics[†]
3. Decide whether to perform a boot operation or not[†]

Discovering Removable MMC4.3 Boot Mode Support

For removable MMC4.3 cards, the software driver must perform the following steps:[†]

1. Discover the card as described in *Enumerated Card Stack*.[†]
2. Read the MMC card device's EXT_CSD registers and examine the following fields:[†]
 - `BOOT_PARTITION_ENABLE`[†]
 - `BOOT_SIZE_MULT`[†]
 - `BOOT_INFO`[†]

Note: For more information, refer to "Access to Boot Partition" in JEDEC Standard No. JESD84-A43, available on the JEDEC website.[†]

3. If the host processor needs to perform a boot operation at the next power-up cycle, it can manipulate the contents of the EXT_CSD registers in the MMC card device, by using a `SWITCH_FUNC` command.[†]
4. After this step, the software driver must power down the card by writing to the `pwren` register.[†]
5. From here on, use the same steps as in *Alternative Boot Operation for eMMC Card Devices*.[†]

Note: Ignore the EBE if it is generated during an abort scenario.

If a boot acknowledge error occurs, the boot acknowledge received interrupt times out.[†]

In internal DMA controller mode, the application needs to depend on the descriptor close interrupt instead of the data done interrupt. †

11	ceata_device_interrupt_status	<p>Software should appropriately write to this bit after power-on reset or any other reset to CE-ATA device. After reset, usually CE-ATA device interrupt is disabled (nIEN = 1). If the host enables CE-ATA device interrupt, then software should set this bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Interrupts not enabled in CE-ATA device</td> </tr> <tr> <td>0x1</td> <td>Interrupts are enabled in CE-ATA device</td> </tr> </tbody> </table>	Value	Description	0x0	Interrupts not enabled in CE-ATA device	0x1	Interrupts are enabled in CE-ATA device	RW	0x0
Value	Description									
0x0	Interrupts not enabled in CE-ATA device									
0x1	Interrupts are enabled in CE-ATA device									
10	send_auto_stop_ccsd	<p>Always set send_auto_stop_ccsd and send_ccsd bits together; send_auto_stop_ccsd should not be set independent of send_ccsd. When set, SD/MMC automatically sends internally generated STOP command (CMD12) to CE-ATA device. After sending internally-generated STOP command, Auto Command Done (ACD) bit in RINTSTS is set and generates interrupt to host if Auto CommandDone interrupt is not masked. After sending the CCSD, SD/MMC automatically clears send_auto_stop_ccsd bit.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Clear bit if SD/MMC does not reset the bit</td> </tr> <tr> <td>0x1</td> <td>Send internally generated STOP.</td> </tr> </tbody> </table>	Value	Description	0x0	Clear bit if SD/MMC does not reset the bit	0x1	Send internally generated STOP.	RW	0x0
Value	Description									
0x0	Clear bit if SD/MMC does not reset the bit									
0x1	Send internally generated STOP.									

Bit	Name	Description	Access	Reset						
9	send_ccsd	<p>When set, SD/MMC sends CCSD to CE-ATA device. Software sets this bit only if current command is expecting CCS (that is, RW_BLK) and interrupts are enabled in CE-ATA device. Once the CCSD pattern is sent to device, SD/MMC automatically clears send_ccsd bit. It also sets Command Done (CD) bit in RINTSTS register and generates interrupt to host if Command Done interrupt is not masked. NOTE: Once send_ccsd bit is set, it takes two card clock cycles to drive the CCSD on the CMD line. Due to this, during the boundary conditions it may happen that CCSD is sent to the CE-ATA device, even if the device signalled CCS.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Clear bit if SD/MMC does not reset the bit</td> </tr> <tr> <td>0x1</td> <td>Send Command Completion Signal Disable (CCSD) to CE-ATA device</td> </tr> </tbody> </table>	Value	Description	0x0	Clear bit if SD/MMC does not reset the bit	0x1	Send Command Completion Signal Disable (CCSD) to CE-ATA device	RW	0x0
Value	Description									
0x0	Clear bit if SD/MMC does not reset the bit									
0x1	Send Command Completion Signal Disable (CCSD) to CE-ATA device									
8	abort_read_data	<p>After suspend command is issued during read-transfer, software polls card to find when suspend happened. Once suspend occurs software sets bit to reset data state-machine, which is waiting for next block of data. Bit automatically clears once data statemachine resets to idle. Used in SDIO card suspend sequence.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No change</td> </tr> <tr> <td>0x1</td> <td>Abort Read</td> </tr> </tbody> </table>	Value	Description	0x0	No change	0x1	Abort Read	RW	0x0
Value	Description									
0x0	No change									
0x1	Abort Read									
7	send_irq_response	<p>Bit automatically clears once response is sent. To wait for MMC card interrupts, host issues CMD40, and SD/MMC waits for interrupt response from MMC card(s). In meantime, if host wants SD/MMC to exit waiting for interrupt state, it can set this bit, at which time SD/MMC command state-machine sends CMD40 response on bus and returns to idle state.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No change</td> </tr> <tr> <td>0x1</td> <td>Send auto IRQ response</td> </tr> </tbody> </table>	Value	Description	0x0	No change	0x1	Send auto IRQ response	RW	0x0

clkena Fields

Bit	Name	Description	Access	Reset						
16	cclk_low_power	In low-power mode, stop sdmmc_cclk_out when card in IDLE (should be normally set to only MMC and SD memory cards; for SDIO cards, if interrupts must be detected, clock should not be stopped). <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Non-low-power mode</td></tr> <tr> <td>0x1</td><td>Low-power mode</td></tr> </tbody> </table>	Value	Description	0x0	Non-low-power mode	0x1	Low-power mode	RW	0x0
Value	Description									
0x0	Non-low-power mode									
0x1	Low-power mode									
0	cclk_enable	Enables sdmmc_cclk_out. <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>SD/MMC Disable</td></tr> <tr> <td>0x1</td><td>SD/MMC Enable</td></tr> </tbody> </table>	Value	Description	0x0	SD/MMC Disable	0x1	SD/MMC Enable	RW	0x0
Value	Description									
0x0	SD/MMC Disable									
0x1	SD/MMC Enable									

tmout

Sets timeout values

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704014

Offset: 0x14

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
data_timeout RW 0xFFFFFFFF															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
data_timeout RW 0xFFFFFFFF								response_timeout RW 0x40							

tmout Fields

Bit	Name	Description	Access	Reset
31:8	data_timeout	Value for card Data Read Timeout; same value also used for Data Starvation by Host timeout. Value is in number of card output clocks sdmmc_cclk_out of selected card.	RW	0xFFFFFFFF F
7:0	response_timeout	Response timeout value. Value is in number of card output clocks sdmmc_cclk_out.	RW	0x40

ctype

Describes card formats.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704018

Offset: 0x18

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
byte_count															
RW 0x200															

bytcnt Fields

Bit	Name	Description	Access	Reset
31:0	byte_count	This value should be an integer multiple of the Block Size for block transfers. For undefined number of byte transfers, byte count should be set to 0. When byte count is set to 0, it is responsibility of host to explicitly send stop/abort command to terminate data transfer. Note: In SDIO mode, if a single transfer is greater than 4 bytes and non-DWORD-aligned, the transfer should be broken where only the last transfer is non-DWORD-aligned and less than 4 bytes. For example, if a transfer of 129 bytes must occur, then the driver should start at least two transfers; one with 128 bytes and the other with 1 byte.	RW	0x200

intmask

Allows Masking of Various Interrupts

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset						
23	ccs_expected	<p>If the command expects Command Completion Signal (CCS) from the CE-ATA device, the software should set this control bit. SD/MMC sets Data Transfer Over (DTO) bit in RINTSTS register and generates interrupt to host if Data Transfer Over interrupt is not masked.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device</td> </tr> <tr> <td>0x1</td> <td>Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device</td> </tr> </tbody> </table>	Value	Description	0x0	Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device	0x1	Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device	RW	0x0
Value	Description									
0x0	Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device									
0x1	Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device									
22	read_ceata_device	<p>Software should set this bit to indicate that CE-ATA device is being accessed for read transfer. This bit is used to disable read data timeout indication while performing CE-ATA read transfers. Maximum value of I/O transmission delay can be no less than 10 seconds. SD/MMC should not indicate read data timeout while waiting for data from CE-ATA device.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Host is not performing read access (RW_REG or RW_BLK) towards CE-ATA device</td> </tr> <tr> <td>0x1</td> <td>Host is performing read access (RW_REG or RW_BLK) towards CE-ATA device</td> </tr> </tbody> </table>	Value	Description	0x0	Host is not performing read access (RW_REG or RW_BLK) towards CE-ATA device	0x1	Host is performing read access (RW_REG or RW_BLK) towards CE-ATA device	RW	0x0
Value	Description									
0x0	Host is not performing read access (RW_REG or RW_BLK) towards CE-ATA device									
0x1	Host is performing read access (RW_REG or RW_BLK) towards CE-ATA device									

Bit	Name	Description	Access	Reset						
21	update_clock_registers_only	<p>Following register values transferred into card clock domain: CLKDIV, CLRSRC, CLKENA. Changes card clocks (change frequency, truncate off or on, and set low-frequency mode); provided in order to change clock frequency or stop clock without having to send command to cards. During normal command sequence, when update_clock_registers_only = 0, following control registers are transferred from BIU to CIU: CMD, CMDARG, TMOU, CTYPE, BLKSIZ, BYTCNT. CIU uses new register values for new command sequence to card(s). When bit is set, there are no Command Done interrupts because no command is sent to SD_MMC_CEATA cards.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Normal command sequence</td> </tr> <tr> <td>0x1</td> <td>Do not send commands, just update clock register value into card clock domain</td> </tr> </tbody> </table>	Value	Description	0x0	Normal command sequence	0x1	Do not send commands, just update clock register value into card clock domain	RW	0x0
Value	Description									
0x0	Normal command sequence									
0x1	Do not send commands, just update clock register value into card clock domain									
20:16	card_number	Card number in use must always be 0.	RW	0x0						
15	send_initialization	<p>After power on, 80 clocks must be sent to the card for initialization before sending any commands to card. Bit should be set while sending first command to card so that controller will initialize clocks before sending command to card. This bit should not be set for either of the boot modes (alternate or mandatory).</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Do not send initialization sequence (80 clocks of 1) before sending this command</td> </tr> <tr> <td>0x1</td> <td>Send initialization sequence before sending this command</td> </tr> </tbody> </table>	Value	Description	0x0	Do not send initialization sequence (80 clocks of 1) before sending this command	0x1	Send initialization sequence before sending this command	RW	0x0
Value	Description									
0x0	Do not send initialization sequence (80 clocks of 1) before sending this command									
0x1	Send initialization sequence before sending this command									

Bit	Name	Description	Access	Reset						
14	stop_abort_cmd	<p>When open-ended or predefined data transfer is in progress, and host issues stop or abort command to stop data transfer, bit should be set so that command/data state-machines of CIU can return correctly to idle state. This is also applicable for Boot mode transfers. To Abort boot mode, this bit should be set along with CMD[26] = disable_boot. Note: If abort is sent to function-number currently selected or not in data-transfer mode, then bit should be set to 0.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Don't stop or abort command to stop current data transfer in progress</td> </tr> <tr> <td>0x1</td> <td>Stop or Abort command, intended to stop current data transfer in progress</td> </tr> </tbody> </table>	Value	Description	0x0	Don't stop or abort command to stop current data transfer in progress	0x1	Stop or Abort command, intended to stop current data transfer in progress	RW	0x0
Value	Description									
0x0	Don't stop or abort command to stop current data transfer in progress									
0x1	Stop or Abort command, intended to stop current data transfer in progress									
13	wait_prvdata_complete	<p>Determines when command is sent. The send command at once option is typically used to query status of card during data transfer or to stop current data transfer.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Send command at once</td> </tr> <tr> <td>0x1</td> <td>Wait for previous data transfer completion</td> </tr> </tbody> </table>	Value	Description	0x0	Send command at once	0x1	Wait for previous data transfer completion	RW	0x0
Value	Description									
0x0	Send command at once									
0x1	Wait for previous data transfer completion									
12	send_auto_stop	<p>When set, SD/MMC sends stop command to SD/MMC_CEATA cards at end of data transfer. Determine the following: *-when send_auto_stop bit should be set, since some data transfers do not need explicit stop commands. *-open-ended transfers that software should explicitly send to stop command. Additionally, when resume is sent to resume-suspended memory access of SD-Combo card, bit should be set correctly if suspended data transfer needs send_auto_stop. Don't care if no data expected from card.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No stop command sent at end of data transfer</td> </tr> <tr> <td>0x1</td> <td>Send stop command at end of data transfer</td> </tr> </tbody> </table>	Value	Description	0x0	No stop command sent at end of data transfer	0x1	Send stop command at end of data transfer	RW	0x0
Value	Description									
0x0	No stop command sent at end of data transfer									
0x1	Send stop command at end of data transfer									

Bit	Name	Description	Access	Reset						
11	transfer_mode	Block transfer command. Don't care if no data expected <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Block data transfer command</td> </tr> <tr> <td>0x1</td> <td>Stream data transfer command</td> </tr> </tbody> </table>	Value	Description	0x0	Block data transfer command	0x1	Stream data transfer command	RW	0x0
Value	Description									
0x0	Block data transfer command									
0x1	Stream data transfer command									
10	read_write	Read/Write from card. Don't care if no data transfer expected. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Read from card</td> </tr> <tr> <td>0x1</td> <td>Write to card</td> </tr> </tbody> </table>	Value	Description	0x0	Read from card	0x1	Write to card	RW	0x0
Value	Description

30:28	dw_dma_multiple_transaction_size	<p>Burst size of multiple transaction; should be programmed same as DMA controller multiple-transaction-size SRC/DEST_MSIZE. The units for transfers is 32 bits. A single transfer would be signalled based on this value. Value should be sub-multiple of 512. Allowed combinations for MSize and TX_WMark.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Msize 1 and TX_WMARK 1-1023</td> </tr> <tr> <td>0x1</td> <td>Msize 4 and TX_WMARK 256</td> </tr> <tr> <td>0x2</td> <td>Msize 8 and TX_WMARK 128</td> </tr> <tr> <td>0x3</td> <td>Msize 16 and TX_WMARK 64</td> </tr> <tr> <td>0x5</td> <td>Msize 1 and RX_WMARK 512</td> </tr> <tr> <td>0x6</td> <td>Msize 4 and RX_WMARK 128</td> </tr> <tr> <td>0x7</td> <td>Msize 8 and RX_WMARK 64</td> </tr> </tbody> </table>	Value	Description	0x0	Msize 1 and TX_WMARK 1-1023	0x1	Msize 4 and TX_WMARK 256	0x2	Msize 8 and TX_WMARK 128	0x3	Msize 16 and TX_WMARK 64	0x5	Msize 1 and RX_WMARK 512	0x6	Msize 4 and RX_WMARK 128	0x7	Msize 8 and RX_WMARK 64	RW	0x0
Value	Description																			
0x0	Msize 1 and TX_WMARK 1-1023																			
0x1	Msize 4 and TX_WMARK 256																			
0x2	Msize 8 and TX_WMARK 128																			
0x3	Msize 16 and TX_WMARK 64																			
0x5	Msize 1 and RX_WMARK 512																			
0x6	Msize 4 and RX_WMARK 128																			
0x7	Msize 8 and RX_WMARK 64																			
27:16	rx_wmark	<p>FIFO threshold watermark level when receiving data to card. When FIFO data count reaches greater than this number, DMA/FIFO request is raised. During end of packet, request is generated regardless of threshold programming in order to complete any remaining data. In non-DMA mode, when receiver FIFO threshold (RXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, interrupt is not generated if threshold programming is larger than any remaining data. It is responsibility of host to read remaining bytes on seeing Data Transfer Done interrupt. In DMA mode, at end of packet, even if remaining bytes are less than threshold, DMA request does single transfers to flush out any remaining bytes before Data Transfer Done interrupt is set. 12 bits - 1 bit less than FIFO-count of status register, which is 13 bits. Limitation: RX_WMark <= 1022 Recommended: 511; means greater than (FIFO_DEPTH/2) - 1) NOTE: In DMA mode during CCS time-out, the DMA does not generate the request at the end of packet, even if remaining bytes are less than threshold. In this case, there will be some data left in the FIFO. It is the responsibility of the application to reset the FIFO after the CCS timeout.</p>	RW	0x3FF																

Bit	Name	Description	Access	Reset
11:0	tx_wmark	FIFO threshold watermark level when transmitting data to card. When FIFO data count is less than or equal to this number, DMA/FIFO request is raised. If Interrupt is enabled, then interrupt occurs. During end of packet, request or interrupt is generated, regardless of threshold programming. In non-DMA mode, when transmit FIFO threshold (TXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, on last interrupt, host is responsible for filling FIFO with only required remaining bytes (not before FIFO is full or after CIU completes data transfers, because FIFO may not be empty). In DMA mode, at end of packet, if last transfer is less than burst size, DMA controller does single cycles until required bytes are transferred. 12 bits - 1 bit less than FIFO-count of status register, which is 13 bits. Limitation: TX_WMark >= 1; Recommended: FIFO_DEPTH/2 = 512; (means less than or equal to 512)	RW	0x0

Bit	Name	Description	Access	Reset						
0	volt_reg	Determines the voltage fed to the buffers by an external voltage regulator. These bits function as the output of the host controller and are fed to an external voltage regulator. The voltage regulator must switch the voltage of the buffers of a particular card to either 3.3V or 1.8V, depending on the value programmed in the register. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Buffers supplied with 3.3V Vdd</td> </tr> <tr> <td>0x1</td> <td>Buffers supplied with 1.8V Vdd</td> </tr> </tbody> </table>	Value	Description	0x0	Buffers supplied with 3.3V Vdd	0x1	Buffers supplied with 1.8V Vdd	RW	0x0
Value	Description									
0x0	Buffers supplied with 3.3V Vdd									
0x1	Buffers supplied with 1.8V Vdd

The hard processor system (HPS) provides a quad serial peripheral interface (SPI) flash controller for access to serial NOR flash devices. The quad SPI flash controller supports standard SPI flash devices as well as high-performance dual and quad SPI flash devices. The quad SPI flash controller is based on Cadence Quad SPI Flash Controller (QSPI_FLASH_CTRL).

Features of the Quad SPI Flash Controller

The quad SPI flash controller supports the following features:

- Single, dual, and quad I/O commands
- Device frequencies up to 108 MHz^(*)
- Direct access and indirect access modes
- External direct memory access (DMA) controller support for indirect transfers
- Configurable clock polarity and phase
- Programmable write-protected regions
- Programmable delays between transactions
- Programmable device sizes
- Read data capture tuning
- Local buffering with error correction code (ECC) logic for indirect transfers
- Up to four devices
-
- Supports the Micron N25Q512A (512 MB, 108 MHz) and Micron N25Q00AA (1024 MB, 108 MHz) Quad SPI flash memories that have been verified to work properly with the HPS.
- eXecute-In-Place (XIP) mode

(*) The quad SPI controller supports any device frequencies, but this speed is limited by the supported flash devices.

Quad SPI Flash Controller Block Diagram and System Integration

Figure 15-1: Quad SPI Flash Controller Block Diagram and System Integration

The quad SPI controller consists of the following blocks and interfaces:

- Register slave interface—Slave interface that provides access to the control and status registers (CSRs)
- Data slave controller—Slave interface and controller that provides the following functionality:
 - Performs data transfers to and from the level 3 (L3) interconnect
 - Validates incoming accesses
 - Performs byte or half-word reordering
 - Performs write protection
 - Forwards transfer requests to direct and indirect controller
- Direct access controller—provides memory-mapped slaves direct access to the flash memory
- Indirect access controller—provides higher-performance access to the flash memory through local buffering and software transfer requests

- Software triggered instruction generator (STIG)—generates flash commands through the flash command register (`flashcmd`) and provides low-level access to flash memory
- Flash command generator—generates flash command and address instructions based on instructions from the direct and indirect access controllers or the STIG
- DMA peripheral request controller—issues requests to the DMA peripheral request interface to communicate with the external DMA controller
- SPI PHY—serially transfers data and commands to the external SPI flash devices

Functional Description of the Quad SPI Flash Controller

Overview

The quad SPI flash controller uses the register slave interface to select the operation modes and configure the data slave interface for data transfers. The quad SPI flash controller uses the data slave interface for direct and indirect accesses, and the register slave interface for software triggered instruction generator (STIG) operation and SPI legacy mode accesses.

Accesses to the data slave are forwarded to the direct or indirect access controller. If the access address is within the configured indirect address range, the access is sent to the indirect access controller.

Data Slave Interface

The quad SPI flash controller uses the data slave interface for direct, indirect, and SPI legacy mode accesses.

The data slave interface is 32 bits wide and permits byte, half-word, and word accesses. For write accesses, incrementing burst lengths of 1, 4, 8 and 16 are supported. For read accesses, all burst types and sizes are supported.

Direct Access Mode

Direct access mode is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming AMBA data slave interface access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and is serviced by the direct access controller.

Note: Accesses that use the direct access controller do not use the embedded SRAM.

Data Slave Remapping Example

Figure 15-2: Data Slave Remapping Example

To remap the data slave to access other 1 MB regions of the flash device, enable address remapping in the enable ARM[®] AMBA[®] advanced high speed bus (AHB) address remapping field (*enahbremap*) of the *cfg* register. All incoming data slave accesses remap to the offset specified in the remap address register (*remapaddr*).

The 20 LSBs of incoming addresses are used for accessing the 1 MB region and the higher bits are ignored.

Note: The quad SPI controller does not issue any error status for accesses that lie outside the connected flash memory space.

AHB

The data slave interface is throttled as the read or write burst is carried out. The latency is designed to be as small as possible and is kept to a minimum when the use of XIP read instructions are enabled.

FLASH erase operations, which may be required before a page write, are triggered by software using the documented programming interface. They are not issued automatically.

Once a page program cycle has been started, the QSPI Flash Controller will automatically poll for the write cycle to complete before allowing any further data slave interface accesses to complete. This is achieved by holding any subsequent AHB direct accesses in wait state.

Indirect Access Mode

In indirect access mode, flash data is temporarily buffered in the quad SPI controller's static RAM (SRAM). Software controls and triggers indirect accesses through the register slave interface. The controller transfers data through the data slave interface.

Indirect Read Operation

An indirect read operation reads data from the flash memory, places the data into the SRAM, and transfers the data to an external master through the data slave interface. The indirect read operations are controlled by the following registers:

- Indirect read transfer register (`indrđ`)
- Indirect read transfer watermark register (`indrđwater`)
- Indirect read transfer start address register (`indrđstaddr`)
- Indirect read transfer number bytes register (`indrđcnt`)
- Indirect address trigger register (`indaddrtrig`)

These registers need to be configured prior to issuing indirect read operations. The start address needs to be defined in the `indrđstaddr` register and the total number of bytes to be fetched is specified in the `indrđcnt` register. Writing 1 to the start indirect read bit (`start`) of the `indrđ` register triggers the indirect read operation from the flash memory to populate the SRAM with the returned data.

To read data from the flash device into the SRAM, an external master issues 32-bit read transactions to the data slave interface. The address of the read access must be in the indirect address range. You can configure the indirect address through the `indaddrtrig` register. The external master can issue 32-bit reads until the last word of an indirect transfer. On the final read, the external master may issue a 32-bit, 16-bit or 8-bit read to complete the transfer. If there are less than four bytes of data to read on the last transfer, the external master can still issue a 32-bit read and the quad SPI controller will pad the upper bits of the response data with zeros.

Assuming the requested data is present in the SRAM at the time the data slave read is received by the quad SPI controller, the data is fetched from SRAM and the response to the read burst is achieved with minimum latency. If the requested data is not immediately present in the SRAM, the data slave interface enters a wait state until the data has been read from flash memory into SRAM. Once the data has been read from SRAM by the external master, the quad SPI controller frees up the associated resource in the SRAM. If the SRAM is full, reads on the SPI interface are backpressured until space is available in the SRAM. The quad SPI controller completes any current read burst, waits for SRAM to free up, and issues a new read burst at the address where the previous burst was terminated.

The processor can also use the SRAM fill level in the SRAM fill register (`sramfill`) to control when data should be fetched from the SRAM.

Another alternative is to use the fill level watermark of the SRAM, which you configure in the `indrđwater` register. When the SRAM fill level passes the watermark level, the indirect transfer watermark interrupt is generated. You can disable the watermark feature by writing zero to the `indrđwater` register.

For the final bytes of data read by the quad SPI controller and placed in the SRAM, if the watermark level is greater than zero, the indirect transfer watermark interrupt is generated even when the actual SRAM fill level has not risen above the watermark.

If the address of the read access is outside the range of the indirect trigger address, one of the following actions occurs:

- When direct access mode is enabled, the read uses direct access mode.
- When direct access mode is disabled, the slave returns an error back to the requesting master.

You can cancel an indirect operation by setting the cancel indirect read bit (`cancel`) of the `indrđ` register to 1. For more information, refer to the “*Indirect Read Operation with DMA Disabled*” section.

Related Information

[Indirect Read Operation with DMA Disabled](#) on page 15-15

Indirect Write Operation

An indirect write operation programs data from the SRAM to the flash memory. The indirect write operations are controlled by the following registers:

- Indirect write transfer register (`indwr`)
- Indirect write transfer watermark register (`indwrwater`)
- Indirect write transfer start address register (`indwrstaddr`)
- Indirect write transfer number bytes register (`indwrcnt`)
- `indaddrtrig` register

These registers need to be configured prior to issuing indirect write operations. The start address needs to be defined in the `indwrstaddr` register and the total number of bytes to be written is specified in the `indwrcnt` register. The start indirect write bit (`start`) of the `indwr` register triggers the indirect write operation from the SRAM to the flash memory.

To write data from the SRAM to the flash device, an external master issues 32-bit write transactions to the data slave. The address of the write access must be in the indirect address range. You can configure the indirect address through the `indaddrtrig` register. The external master can issue 32-bit writes until the last word of an indirect transfer. On the final write, the external master may issue a 32-bit, 16-bit or 8-bit write to complete the transfer. If there are less than four bytes of data to write on the last transfer, the external master can still issue a 32-bit write and the quad SPI controller discards the extra bytes.

The SRAM size can limit the amount of data that the quad SPI controller can accept from the external master. If the SRAM is not full at the point of the write access, the data is pushed to the SRAM with minimum latency. If the external master attempts to push more data to the SRAM than the SRAM can accept, the quad SPI controller backpressures the external master with wait states. When the SRAM resource is freed up by pushing the data from SRAM to the flash memory, the SRAM is ready to receive more data from the external master. When the SRAM holds an equal or greater number of bytes than the size of a flash page, or when the SRAM holds all the remaining bytes of the current indirect transfer, the quad SPI controller initiates a write operation to the flash memory.

The processor can also use the SRAM fill level, in the `sramfill` register, to control when to write more data into the SRAM.

Alternatively, you can configure the fill level watermark of the SRAM in the `indwrwater` register. When the SRAM fill level falls below the watermark level, an indirect transfer watermark interrupt is generated to tell software to write the next page of data to SRAM. Because the quad SPI controller initiates non-end-of-data writes to the flash memory only when the SRAM contains a full flash page of data, you must set the watermark level to a value greater than one flash page to avoid the system stalling. You can disable the watermark feature by writing zero to the `indwrwater` register.

If the address of the write access is outside the range of the indirect trigger address, one of the following actions occurs:

- When direct access mode is enabled, the write uses direct access mode.
- When direct access mode is disabled, the slave returns an error back to the requesting master.

You can cancel an indirect operation by setting the cancel indirect write bit (`cancel`) of the `indwr` register to 1. For more information, refer to the “*Indirect Write Operation with DMA Disabled*” section.

Related Information

[Indirect Write Operation with DMA Disabled](#) on page 15-16

Consecutive Reads and Writes

It is possible to trigger two indirect operations at a time by triggering the `start` bit of the `indrđ` or `indwr` register twice in short succession. The second operation can be triggered while the first operation is in

progress. For example, software may trigger an indirect read or write operation while an indirect write operation is in progress. The corresponding start and count registers must be configured properly before software triggers each transfer operation.

This approach allows for a short turnaround time between the completion of one indirect operation and the start of a second operation. Any attempt to queue more than two operations causes the indirect read reject interrupt to be generated.

SPI Legacy Mode

SPI legacy mode allows software to access the internal TX FIFO and RX FIFO buffers directly, thus bypassing the direct, indirect and STIG controllers. Software accesses the TX FIFO and RX FIFO buffers by writing any value to any address through the data slave while legacy mode is enabled. You can enable legacy mode with the legacy IP mode enable bit (`enlegacyip`) of the `cfg` register.

Legacy mode allows the user to issue any flash instruction to the flash device, but imposes a heavy software overhead in order to manage the fill levels of the FIFO buffers effectively. The legacy SPI mode is bidirectional in nature, with data continuously being transferred both directions while the chip select is enabled. If the driver only needs to read data from the flash device, dummy data must be written to ensure the chip select stays active, and vice versa for write transactions.

For example, to perform a basic read of four bytes to a flash device that has three address bytes, software must write a total of eight bytes to the TX FIFO buffer. The first byte would be the instruction opcode, the next three bytes are the address, and the final four bytes would be dummy data to ensure the chip select stays active while the read data is returned. Similarly, because eight bytes were written to the TX FIFO buffer, software should expect eight bytes to be returned in the RX FIFO buffer. The first four bytes of this would be discarded, leaving the final four bytes holding the data read from the device.

Because the TX FIFO and RX FIFO buffers are four bytes deep each, software must maintain the FIFO buffer levels to ensure the TX FIFO buffer does not underflow and the RX FIFO buffer does not overflow. Interrupts are provided to indicate when the fill levels pass the watermark levels, which are configurable through the TX threshold register (`txthresh`) and RX threshold register (`rxthresh`).

Register Slave Interface

The quad SPI flash controller uses the register slave interface to configure the quad SPI controller through the quad SPI configuration registers, and to access flash memory under software control, through the `flashcmd` register in the STIG.

STIG Operation

The Software Triggered Instruction Generator (STIG) is used to access the volatile and non-volatile configuration registers, the legacy SPI status register, and other status and protection registers. The STIG also is used to perform ERASE functions. The direct and indirect access controllers are used only to transfer data. The `flashcmd` register uses the following parameters to define the command to be issued to the flash device:

- Instruction opcode
- Number of address bytes
- Number of dummy bytes
- Number of write data bytes
- Write data
- Number of read data bytes

The address is specified through the flash command address register (`flashcmdaddr`). Once these settings have been specified, software can trigger the command with the execute command field (`execcmd`) of the

`flashcmd` register and wait for its completion by polling the command execution status bit (`cmdexecstat`) of the `flashcmd` register. A maximum of eight data bytes may be read from the flash command read data lower (`flashcmdrddatalo`) and flash command read data upper (`flashcmdrddataup`) registers or written to the flash command write data lower (`flashcmdwrdata_lo`) and flash command write data upper (`flashcmdwrdataup`) registers per command.

Commands issued through the STIG have a higher priority than all other read accesses and therefore interrupt any read commands being requested by the direct or indirect controllers. However, the STIG does not interrupt a write sequence that may have been issued through the direct or indirect access controller. In these cases, it might take a long time for the `cmdexecstat` bit of the `flashcmd` register indicates the operation is complete.

Note: Altera recommends using the STIG instead of the SPI legacy mode to access the flash device registers and perform erase operations.

Local Memory Buffer

The SRAM local memory buffer is a 128 by 32-bit (512 total bytes) memory and includes support for error correction code (ECC). The ECC logic provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes.

The SRAM has two partitions, with the lower partition reserved for indirect read operations and the upper partition for indirect write operations, as shown in [Figure 15-1](#). The size of the partitions is specified in the SRAM partition register (`srampart`), based on 32-bit word sizes. For example, to specify four bytes of storage, write the value 1. The value written to the indirect read partition size field (`addr`) defines the number of entries reserved for indirect read operations. For example, write the value 32 (0x20) to partition the 128-entry SRAM to 32 entries (25%) for read usage and 96 entries (75%) for write usage.

For more information about ECC, refer to the *System Manager* chapter in volume 3 of the Arria® V Device Handbook.

[System Manager](#) on page 5-1

DMA Peripheral Request Controller

The DMA peripheral request controller is only used for the indirect mode of operation where data is temporarily stored in the SRAM. The quad SPI flash controller uses the DMA peripheral request interface to trigger the external DMA into performing data transfers between memory and the quad SPI controller.

There are two DMA peripheral request interfaces, one for indirect reads and one for indirect writes. The DMA peripheral request controller can issue two types of DMA requests, single or burst, to the external DMA. The number of bytes for each single or burst request is specified in the number of single bytes (`numsglreqbytes`) and number of burst bytes (`numburstreqbytes`) fields of the DMA peripheral register (`dmaper`). The DMA peripheral request controller splits the total amount of data to be transferred into a number of DMA burst and single requests by dividing the total number of bytes by the number of bytes specified in the burst request, and then dividing the remainder by the number of bytes in a single request.

Note: When programming the DMA controller, the burst request size must match the burst request size set in the quad SPI controller to avoid quickly reaching an overflow or underflow condition.

For indirect reads, the DMA peripheral request controller only issues DMA requests after the data has been retrieved from flash memory and written to SRAM. The rate at which DMA requests are issued depends on the watermark level. The `indrwater` register defines the minimum fill level in bytes at which the DMA peripheral request controller can issue the DMA request. The higher this number is, the more

data that must be buffered in SRAM before the external DMA moves the data. When the SRAM fill level passes the watermark level, the transfer watermark reached interrupt is generated.

For example, consider the following conditions:

- The total amount of data to be read using indirect mode is 256 bytes
- The SRAM watermark level is set at 128 bytes
- Software configures the burst type transfer size to 64 bytes

Under these conditions, the DMA peripheral request controller issues the first DMA burst request when the SRAM fill level passes 128 bytes (the watermark level). The DMA peripheral request controller triggers consecutive DMA burst requests as long as there is sufficient data in the SRAM to perform burst type requests. In this example, DMA peripheral request controller can issue at least two consecutive DMA burst requests to transfer a total of 128 bytes. If there is sufficient data in the SRAM, the DMA peripheral request controller requests the third DMA burst immediately. Otherwise the DMA peripheral request controller waits for the SRAM fill level to pass the watermark level again to trigger the next burst request. When the watermark level is triggered, there is sufficient data in the SRAM to perform the third and fourth burst requests to complete the entire transaction.

For the indirect writes, the DMA peripheral request controller issues DMA requests immediately after the transfer is triggered and continues to do so until the entire indirect write transfer has been transferred. The rate at which DMA requests are issued depends on the watermark level. The `indwrwater` register defines the maximum fill level in bytes at which the controller can issue the first DMA burst or single request. When the SRAM fill level falls below the watermark level, the transfer watermark reached interrupt is generated. When there is one flash page of data in the SRAM, the quad SPI controller initiates the write operation from SRAM to the flash memory.

Software can disable the DMA peripheral request interface with the `endma` field of the `cfg` register. If a master other than the DMA performs the data transfer for indirect operations, the DMA peripheral request interface must be disabled. By default, the indirect watermark registers are set to zero, which means the DMA peripheral request controller can issue DMA request as soon as possible.

For more information about the HPS DMA controller, refer to the *DMA Controller* chapter in volume 3 of the Arria® V Device Handbook.

Arbitration between Direct/Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

1. The Indirect Access Write
2. The Direct Access Write
3. The STIG
4. The Direct Access Read
5. The Indirect Access Read

Each controller is back pressured while waiting to be serviced.

Configuring the Flash Device

For read and write accesses, software must initialize the device read instruction register (`devrd`) and the device write instruction register (`devwr`). These registers include fields to initialize the instruction opcodes that should be used as well as the instruction type, and whether the instruction uses single, dual or quad pins for address and data transfer. To ensure the quad SPI controller can operate from a reset state, the opcode registers reset to opcodes compatible with single I/O flash devices.

The quad SPI flash controller uses the instruction transfer width field (`instwidth`) of the `devrd` register to set the instruction transfer width for both reads and writes. There is no `instwidth` field in the `devwr` register. If instruction type is set to dual or quad mode, the address transfer width (`addrwidth`) and data transfer width (`datawidth`) fields of both registers are redundant because the address and data type is based on the instruction type. Thus, software can support the less common flash instructions where the opcode, address, and data are sent on two or four lanes. For most instructions, the opcodes are sent serially to the flash device, even for dual and quad instructions. One of the flash devices that supports instructions that can send the opcode over two or four lanes is the Micron N25Q128. For reference, [Table 15-1](#) and [Table 15-2](#) show how software should configure the quad SPI controller for each specific read and write instruction, respectively, supported by the Micron N25Q128 device.

Table 15-1: Quad SPI Configuration for Micron N25Q128 Device (Read Instructions)

Instruction	Lanes Used By Opcode	Lanes Used to Send Address	Lanes Used to Send Data	instwidth Value	addrwidth Value	datawidth Value
Read	1	1	1	0	0	0
Fast read	1	1	1	0	0	0
Dual output fast read (DOFR)	1	1	2	0	0	1
Dual I/O fast read (DIOFR)	1	2	2	0	1	1
Quad output fast read (QOFR)	1	1	4	0	0	2
Quad I/O fast read (QIOFR)	1	4	4	0	2	2
Dual command fast read (DCFR)	2	2	2	1	Don't care	Don't care
Quad command fast read (QCFR)	4	4	4	2	Don't care	Don't care

Table 15-2: Quad SPI Configuration for Micron N25Q128 Device (Write Instructions)

Instruction	Lanes Used By Opcode	Lanes Used to Send Address	Lanes Used to Send Data	instwidth Value	addrwidth Value	datawidth Value
Page program	1	1	1	0	0	0
Dual input fast program (DIFP)	1	1	2	0	0	1
Dual input extended fast program (DIEFP)	1	2	2	0	1	1
Quad input fast program (QIFP)	1	1	4	0	0	2
Quad input extended fast program (QIEFP)	1	4	4	0	2	2
Dual command fast program (DCFP)	2	2	2	1	Don't care	Don't care
Quad command fast program (QCFP)	4	4	4	2	Don't care	Don't care

XIP Mode

The quad SPI controller supports XIP mode, if the flash devices support XIP mode. Depending on the flash device, XIP mode puts the flash device in read-only mode, reducing command overhead.

The quad SPI controller must instruct the flash device to enter XIP mode by sending the mode bits. When the enter XIP mode on next read bit (*enterxipnextrd*) of the *cfg* register is set to 1, the quad SPI controller and the flash device are ready to enter XIP mode on the next read instruction. When the enter XIP mode immediately bit (*enterxipimm*) of the *cfg* register is set to 1, the quad SPI controller and flash device enter XIP mode immediately.

When the *enterxipnextrd* or *enterxipimm* bit of the *cfg* register is set to 0, the quad SPI controller and flash device exit XIP mode on the next read instruction. For more information, refer to the “*XIP Mode Operations*” section.

Related Information

[XIP Mode Operations](#) on page 15-17

Write Protection

You can program the controller to write protect a specific region of the flash device. The protected region is defined as a set of blocks, specified by a starting and ending block. Writing to an area of protected flash region memory generates an error and triggers an interrupt.

You define the block size by specifying the number of bytes per block through the number of bytes per block field (*bytespersubsector*) of the device size register (*devsz*). The lower write protection register

(`lowwrprot`) specifies the first flash block in the protected region. The upper write protection register (`upwrprot`) specifies the last flash block in the protected region.

The write protection enable bit (`en`) of the write protection register (`wrprot`) enables and disables write protection. The write protection inversion bit (`inv`) of the `wrprot` register flips the definition of protection so that the region specified by `lowwrprt` and `upwrprt` is unprotected and all flash memory outside that region is protected.

Data Slave Sequential Access Detection

The quad SPI flash controller detects sequential accesses to the data slave interface by comparing the current access with the previous access. An access is sequential when it meets the following conditions:

- The address of the current access sequentially follows the address of the previous access.
- The direction of the current access (read or write) is the same as previous access.
- The size of the current access (byte, half-word, or word) is the same as previous access.

When the access is detected as nonsequential, the sequential access to the flash device is terminated and a new sequential access begins. Altera recommends accessing the data slave sequentially. Sequential access has less command overhead, and therefore, increases data throughput.

Clocks

There are two clock inputs to the quad SPI controller (`l4_mp_clk` and `qspi_clk`) and one clock output (`sclk_out`). The quad SPI flash controller uses the `l4_mp_clk` clock to clock the data slave transfers and register slave accesses. The `qspi_clk` clock is the reference clock for the quad SPI controller and is used to serialize the data and drive the external SPI interface. The `sclk_out` clock is the clock source for the connected flash devices.

The `qspi_clk` clock must be greater than two times the `l4_mp_clk`. The `sclk_out` clock is derived by dividing down the `qspi_clk` clock by the baud rate divisor field (`bauddiv`) of the `cfg` register.

Related Information

[Clock Manager](#) on page 2-1

Resets

A single reset signal (`qspi_flash_rst_n`) is provided as an input to the quad SPI controller. The Reset Manager drives the reset signal to the ECC controller on a cold or warm reset. This resets the logic inside the ECC controller.

Related Information

[Reset Manager](#) on page 3-1

Taking the Quad SPI Flash Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

All interrupt sources are combined to create a single level-sensitive, active-high interrupt (`qspi_intr`). Software can determine the source of the interrupt by reading the interrupt status register (`irqstat`). By

default, the interrupt source is cleared when software writes a one (1) to the interrupt status register. The interrupts are individually maskable through the interrupt mask register (`irqmask`). [Table 15-3](#) lists the interrupt sources in the `irqstat` register.

Table 15-3: Interrupt Sources in the `irqstat` Register

Interrupt Source	Description
Underflow detected	When 0, no underflow has been detected. When 1, the data slave write data is being supplied too slowly. This situation can occur when data slave write data is being supplied too slowly to keep up with the requested write operation. This bit is reset only by a system reset and cleared only when a 1 is written to it.
Indirect operation complete	The controller has completed a triggered indirect operation.
Indirect read reject	An indirect operation was requested but could not be accepted because two indirect operations are already in the queue.
Protected area write attempt	A write to a protected area was attempted and rejected.
Illegal data slave access detected	An illegal data slave access has been detected. Data slave wrapping bursts and the use of split and retry accesses can cause this interrupt. It is usually an indicator that soft masters in the FPGA fabric are attempting to access the HPS in an unsupported way.
Transfer watermark reached	The indirect transfer watermark level has been reached.
Receive overflow	This condition occurs only in legacy SPI mode. When 0, no overflow has been detected. When 1, an overflow to the RX FIFO buffer has occurred. This bit is reset only by a system reset and cleared to zero only when this register is written to. If a new write to the RX FIFO buffer occurs at the same time as a register is read, this flag remains set to 1.
TX FIFO not full	This condition occurs only in legacy SPI mode. When 0, the TX FIFO buffer is full. When 1, the TX FIFO buffer is not full.
TX FIFO full	This condition occurs only in legacy SPI mode. When 0, the TX FIFO buffer is not full. When 1, the TX FIFO buffer is full.

Interrupt Source	Description
RX FIFO not empty	This condition occurs only in legacy SPI mode. When 0, the RX FIFO buffer is empty. When 1, the RX FIFO buffer is not empty.
RX FIFO full	This condition occurs only in legacy SPI mode. When 0, the RX FIFO buffer is not full. When 1, the RX FIFO buffer is full.
Indirect read partition overflow	Indirect Read Partition of SRAM is full and unable to immediately complete indirect operation

Interface Signals

The quad SPI controller provides four chip select outputs to allow control of up to four external quad SPI flash devices. The outputs serve different purposes depending on whether the device is used in single, dual, or quad operation mode. The following table lists the I/O pin use of the quad SPI controller interface signals for each operation mode.

Table 15-4: Interface Signals

Signal	Mode	Direction	Function
data[0]	Single	Output	Data output 0
	Dual or quad	Bidirectional	Data I/O 0
data[1]	Single	Input	Data input 0
	Dual or quad	Bidirectional	Data I/O 1
data[2]	Single or dual	Output	Active low write protect
	Quad	Bidirectional	Data I/O 2
data[3]	Single, dual, or quad	Bidirectional	Data I/O 3
ss_n[0]	Single, dual, or quad	Output	Active low slave select 0
ss_n[1]			Active low slave select 1
ss_n[2]			Active low slave select 2
ss_n[3]			Active low slave select 3
sclk	Single, dual, or quad	Output	Serial Clock

Quad SPI Flash Controller Programming Model

Setting Up the Quad SPI Flash Controller

The following steps describe how to set up the quad SPI controller:

1. Wait until any pending operation has completed.
2. Disable the quad SPI controller with the quad SPI enable field (`en`) of the `cfg` register.
3. Update the `instwidth` field of the `devrd` register with the instruction type you wish to use for indirect and direct writes and reads.
4. If mode bit enable bit (`enmodebits`) of the `devrd` register is enabled, update the mode bit register (`modebit`).
5. Update the `devsz` register as needed. Parts or all of this register might have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing any write. The number of bytes per device block is only required if the write protect feature is used.
6. Update the device delay register (`delay`). This register allows the user to adjust how the chip select is driven after each flash access. Each device may have different timing requirements. If the serial clock frequency is increased, these timing requirements become more critical. The numbers specified in this register are based on the period of the `qspi_clk` clock. For example, on some devices need 50 ns minimum time before the slave select can be reasserted after it has been deasserted. When the device is operating at 100 MHz, the clock period is 10 ns, so 40 ns extra is required. If the `qspi_clk` clock is running at 400 MHz (2.5 ns period), specify a value of at least 16 to the clock delay for chip select deassert field (`nss`) of the `delay` register.
7. Update the `remapaddr` register as needed. This register only affects direct access mode.
8. Set up and enable the write protection registers (`wrprot`, `lowwrprot`, and `upwrprot`), when write protection is required.
9. Enable required interrupts through the `irqmask` register.
10. Set up the `bauddiv` field of the `cfg` register to define the required clock frequency of the target device.
11. Update the read data capture register (`rddatacap`) as needed. This register delays when the read data is captured and can help when the read data path from the device to the quad SPI controller is long and the device clock frequency is high.
12. Enable the quad SPI controller with the `en` field of the `cfg` register.

Indirect Read Operation with DMA Disabled

The following steps describe the general software flow to set up the quad SPI controller for indirect read operation with the DMA disabled:

1. Perform the steps described in the [Setting Up the Quad SPI Flash Controller](#) on page 15-15 section.
2. Set the flash memory start address in the `indrstaddr` register.
3. Set the number of bytes to be transferred in the `indrcont` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set up the required interrupts through the `irqmask` register.
6. If the watermark level is used, set the SRAM watermark level through the `indrwater` register.
7. Start the indirect read operation by setting the `start` field of the `indr` register to 1.

8. Either use the watermark level interrupt or poll the SRAM fill level in the `sramfill` register to determine when there is sufficient data in the SRAM.
9. Issue a read transaction to the indirect address to access the SRAM. Repeat **step 8** if more read transactions are needed to complete the indirect read transfer.
10. Either use the indirect complete interrupt to determine when the indirect read operation has completed or poll the completion status of the indirect read operation through the indirect completion status bit (`ind_ops_done_status`) of the `indr` register.

Related Information

[Setting Up the Quad SPI Flash Controller](#) on page 15-15

Indirect Read Operation with DMA Enabled

The following steps describe the general software flow to set up the quad SPI controller for indirect read operation with the DMA enabled:

1. Perform the steps described in the [Setting Up the Quad SPI Flash Controller](#) on page 15-15 section.
2. Set the flash memory start address in the `indrstaddr` register.
3. Set the number of bytes to be transferred in the `indrcont` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set the number of bytes for single and burst type DMA transfers in the `dmaper` register.
6. Optionally set the SRAM watermark level in the `indrwater` register to control the rate DMA requests are issued.
7. Start an indirect read access by setting the `start` field of the `indr` register to 1.
8. Either use the indirect complete interrupt to determine when the indirect read operation has completed or poll the completion status of the indirect read operation through the `ind_ops_done_status` field of the `indr` register.

Indirect Write Operation with DMA Disabled

The following steps describe the general software flow to set up the quad SPI controller for indirect write operation with the DMA disabled:

1. Perform the steps described in the [Setting Up the Quad SPI Flash Controller](#) on page 15-15 section.
2. Set the flash memory start address in the `indwrstaddr` register.
3. Set up the number of bytes to be transferred in the `indwrcont` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set up the required interrupts through the interrupt mask register (`irqmask`).
6. Optionally set the SRAM watermark level in the `indwrwater` register to control the rate DMA requests are issued. The value set must be greater than one flash page. For more information, refer to the [Indirect Write Operation](#) on page 15-6 section.

7. Start the indirect write operation by setting the `start` field of the `indwr` register to 1.
8. Either use the watermark level interrupt or poll the SRAM fill level in the `sramfill` register to determine when there is sufficient space in the SRAM.
9. Issue a write transaction to the indirect address to write one flash page of data to the SRAM. Repeat [step 8](#) if more write transactions are needed to complete the indirect write transfer. The final write may be less than one page of data.

Indirect Write Operation with DMA Enabled

The following steps describe the general software flow to set up the quad SPI controller for indirect write operation with the DMA enabled:

1. Perform the steps described in the [Setting Up the Quad SPI Flash Controller](#) on page 15-15 section.
2. Set the flash memory start address in the `indwrstaddr` register.
3. Set the number of bytes to be transferred in the `indcnt` field of the `indwr` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set the number of bytes for single and burst type DMA transfers in the `dmaper` register.
6. Optionally set the SRAM watermark level in the `indwrwater` register to control the rate DMA requests are issued. The value set must be greater than one flash page. For more information, refer to the [Indirect Write Operation](#) on page 15-6 section.
7. Start the indirect write access by setting the `start` field of the `indirwr` register to 1.
8. Either use the indirect complete interrupt to determine when the indirect write operation has completed or poll the completion status of the indirect write operation through the `ind_ops_done_status` field of the `indwr` register.

XIP Mode Operations

XIP mode is supported in most SPI flash devices. However, flash device manufacturers do not use a consistent standard approach. Most use signature bits that are sent to the device immediately following the address bytes. Some devices use signature bits and also require a flash device configuration register write to enable XIP mode.

Entering XIP Mode

Micron Quad SPI Flash Devices with Support for Basic-XIP

To enter XIP mode in a Micron quad SPI flash device with support for Basic-XIP, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0x80.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Micron Quad SPI Flash Devices without Support for Basic-XIP

To enter XIP mode in a Micron quad SPI flash device without support for Basic-XIP, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses will be sent to the flash device.
3. Ensure XIP mode is enabled in the flash device by setting the volatile configuration register (VCR) bit 3 to 1. Use the `flashcmd` register to issue the VCR write command.
4. Set the XIP mode bits in the `modebit` register to 0x00.
5. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
6. Re-enable the direct access controller and, if required, the indirect access controller.

Winbond Quad SPI Flash Devices

To enter XIP mode in a Winbond quad SPI flash device, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0x20.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Spansion Quad SPI Flash Devices

To enter XIP mode a Spansion quad SPI flash device, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0xA0.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Exiting XIP Mode

To exit XIP mode, perform the following steps:

1. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
2. Restore the mode bits to the values before entering XIP mode, depending on the flash device and manufacturer.
3. Set the `enterxipnextrd` bit of the `cfg` register to 0.

The flash device must receive a read instruction before it can disable its internal XIP mode state. Thus, XIP mode internally stays active until the next read instruction is serviced. Ensure that XIP mode is disabled before the end of any read sequence.

XIP Mode at Power on Reset

Some flash devices can be XIP-enabled as a nonvolatile configuration setting, allowing the flash device to enter XIP mode at power-on reset (POR) without software intervention. Software cannot discover the XIP state at POR through flash status register reads because an XIP-enabled flash device can only be accessed through the XIP read operation. If you know the device will enter XIP mode at POR, have your initial boot software configure the `modebit` register and set the `enterxipimm` bit of the `cfg` register to 1.

If you do not know in advance whether or not the device will enter XIP mode at POR, have your initial boot software issue an XIP mode exit command through the `flashcmd` register, then follow the steps in the “*Entering XIP Mode*” section. Software must be aware of the mode bit requirements of the device, because XIP mode entry and exit varies by device.

18	enterxipimm	<p>If XIP is enabled, then setting to disabled will cause the controller to exit XIP mode on the next READ instruction. If XIP is disabled, then setting enable will operate the device in XIP mode immediately. Use this register when the external device wakes up in XIP mode (as per the contents of its non-volatile configuration register). The controller will assume the next READ instruction will be passed to the device as an XIP instruction, and therefore will not require the READ opcode to be transferred. Note: To exit XIP mode, this bit should be set to 0. This will take effect in the attached device only after the next READ instruction is executed. Software therefore should ensure that at least one READ instruction is requested after resetting this bit in order to be sure that XIP mode is exited.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr><td>0x1</td><td>Enter XIP Mode immediately</td></tr> <tr><td>0x0</td><td>Exit XIP Mode on next READ instruction</td></tr> </tbody> </table>	Value	Description	0x1	Enter XIP Mode immediately	0x0	Exit XIP Mode on next READ instruction	RW	0x0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
after RW 0x0								init RW 0x0							

delay Fields

Bit	Name	Description	Access	Reset
31:24	nss	Delay in master reference clocks for the length that the master mode chip select outputs are de-asserted between transactions. The minimum delay is always <code>qspi_sck_out</code> period to ensure the chip select is never re-asserted within an <code>qspi_sck_out</code> period.	RW	0x0

Bit	Name	Description	Access	Reset
23:16	btwn	Delay in master reference clocks between one chip select being de-activated and the activation of another. This is used to ensure a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty.	RW	0x0
15:8	after	Delay in master reference clocks between last bit of current transaction and deasserting the device chip select (qspi_n_ss_out). By default, the chip select will be deasserted on the cycle following the completion of the current transaction.	RW	0x0
7:0	init	Delay in master reference clocks between setting qspi_n_ss_out low and first bit transfer.	RW	0x0

flashcmd Fields

Bit	Name	Description	Access	Reset																		
31:24	cmdopcode	The command opcode field should be setup before triggering the command. For example, 0x20 maps to SubSector Erase. Writing to the execute field (bit 0) of this register launches the command. NOTE : Using this approach to issue commands to the device will make use of the instruction type of the device instruction configuration register. If this field is set to 2'b00, then the command opcode, command address, command dummy bytes and command data will all be transferred in a serial fashion. If this field is set to 2'b01, then the command opcode, command address, command dummy bytes and command data will all be transferred in parallel using DQ0 and DQ1 pins. If this field is set to 2'b10, then the command opcode, command address, command dummy bytes and command data will all be transferred in parallel using DQ0, DQ1, DQ2 and DQ3 pins.	RW	0x0																		
23	enrddata	If enabled, the command specified in the command opcode field (bits 31:24) requires read data bytes to be received from the device. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Command Requires read data</td> </tr> <tr> <td>0x0</td> <td>No Action</td> </tr> </tbody> </table>	Value	Description	0x1	Command Requires read data	0x0	No Action	RW	0x0

This chapter describes the direct memory access controller (DMAC) contained in the hard processor system (HPS). The DMAC is used to transfer data between memory and peripherals and other memory locations in the system. The DMA controller is an instance of the ARM CoreLink DMA Controller (DMA-330).

Related Information

<http://infocenter.arm.com/>

For more information about ARM's DMA-330 controller, refer to the *CoreLink DMA Controller DMA-330 Revision: r1p2* Technical Reference Manual on the ARM info center website

Features of the DMA Controller

The HPS provides one DMAC to handle the data transfer between memory-mapped peripherals and memories, off-loading this work from the microprocessor unit (MPU) subsystem.

The DMAC supports multiple transfer types:

- Memory-to-memory
- Memory-to-peripheral
- Peripheral-to-memory

The DMAC supports up to:

- Eight logical channels for different levels of service requirements
- 31 peripheral handshake interfaces for peripheral hardware flow control

The DMAC provides:

ISO
9001:2008
Registered

- An instruction processing block that enables it to process program code that controls a DMA transfer
- An ARM Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) master interface unit to fetch the program code from system memory into its instruction cache

Note: The AXI master interface also performs DMA data transfer. The DMA instruction execution engine executes the program code from its instruction cache and schedules read or write AXI instructions through the respective instruction queues.

- A multi-FIFO (MFIFO) data buffer that stores data that it reads, or writes, during a DMA transfer
- 11 interrupt outputs to enable efficient communication of events to the MPU subsystem

Note: The peripheral request interfaces support the connection of DMA-capable peripherals to enable memory-to-peripheral and peripheral-to-memory transfers to occur, without intervention from the processor. Because, the HPS supports some peripherals that do not comply with ARM DMA peripheral interface protocol, adapters are added to allow these peripherals to work with the DMAC.

The DMAC supports the following interface protocols:

- Synopsys protocol
 - Serial peripheral interface (SPI)
 - Universal asynchronous receiver/transmitter (UART)
 - Inter-integrated circuit (I²C)
 - FPGA
- ARM protocol
 - Quad SPI flash controller
 - System trace macrocell (STM)

Dual slave interfaces enable the operation of the DMA controller to be partitioned into the Secure state and Non-secure state. The network interconnect must be configured to ensure that only secure transactions can access the secure interface. The slave interfaces can access status registers and also directly execute instructions in the DMA controller.

The DMAC has the following features:

- A small instruction set that provides a flexible method of specifying the DMA operations. This architecture provides greater flexibility than the fixed capabilities of a Linked-List Item (LLI) based DMA controller.
- Supports multiple transfer types:
 - Memory-to-memory
 - Memory-to-peripheral
 - Peripheral-to-memory
 - Scatter-gather
- Supports up to eight DMA channels.
- Supports up to eight outstanding AXI read and eight outstanding AXI write transactions.
- Enables software to schedule up to 16 outstanding read and (16) outstanding write instructions.

- Supports (11) interrupt lines into the MPU subsystem:
 - One (1) for DMA thread abort
 - Eight (8) for events
 - Two (2) for MFIFO buffer ECC
- Single and double bit ECC support
- Supports 31 peripheral request interfaces:
 - Eight (8) for FPGA
 - Eight (8) for I²C
 - Eight (8) for SPI
 - Two (2) for quad SPI
 - One (1) for System Trace Macrocell
 - Four (4) for UART

DMA Controller Block Diagram and System Integration

The following figure shows a block diagram of the DMAC and how it integrates into the rest of the HPS system.

Figure 16-1: DMA Controller Connectivity

The `14_main_clk` clock drives the DMA controller, controller logic, and all the interfaces. The DMA controller accesses the level 3 (L3) main switch with its 64-bit AXI master interface.

The DMA controller provides the following slave interfaces:

- Non-secure slave interface
- Secure slave interface

You can use these slave interfaces to access the registers that control the functionality of the DMA controller. The DMA controller implements TrustZone secure technology with one interface operating in the Secure state and the other operating in the Non-secure state.

Functional Description of the DMA Controller

This section describes the major interfaces and components of the DMAC and its operation.

The DMAC contains an instruction processing block that processes program code to control a DMA transfer. The program code is stored in a region of system memory that the DMAC accesses using its AXI master interface. The DMAC stores instructions temporarily in an internal cache.

The DMAC has eight DMA channels. Each channel supports a single concurrent thread of DMA operation. In addition, a single DMA manager thread exists, and you can use it to initialize the DMA channel threads.

The DMAC executes one instruction per clock cycle. To ensure that it regularly executes each active thread, the DMAC alternates by processing the DMA manager thread and then a DMA channel thread. It performs a round-robin process when selecting the next active DMA channel thread to execute.

The DMAC uses variable-length instructions that consist of one to six bytes. It provides a separate program counter (PC) register for each DMA channel.

The DMAC includes a 16-line instruction cache to improve the instruction fetch performance. Each instruction cache line contains eight, four-byte words for a total cache line size of 32 bytes. The DMAC instruction cache size is therefore 16 lines times 32 bytes per line which equals 512 bytes. When a thread requests an instruction from an address, the cache performs a lookup. If a cache hit occurs, then the cache immediately provides the instruction. Otherwise, the thread is stalled while the DMAC performs a cache line fill through the AXI master interface. If an instruction spans the end of a cache line, the DMAC performs multiple cache accesses to fetch the instruction.

Note: When a cache line fill is in progress, the DMAC enables other threads to access the cache. But if another cache miss occurs, the pipeline stalls until the first line fill is complete.

When a DMA channel thread executes a load or store instruction, the DMAC adds the instruction to the relevant read or write queue. The DMAC uses these queues as an instruction storage buffer prior to it issuing the instructions on the AXI. The DMAC also contains an MFIFO data buffer in which it stores data that it reads or writes during a DMA transfer.

The DMAC provides multiple interrupt outputs to enable efficient communication of events to external microprocessors. The peripheral request interfaces support the connection of DMA-capable peripherals to enable memory-to-peripheral and peripheral-to-memory DMA transfers to occur without intervention from a microprocessor.

Dual slave interfaces enable the operation of the DMAC to be partitioned into the Secure state and Non-secure states. You can access status registers and also directly execute instructions in the DMAC with the slave interfaces.

Operating States

The following figure shows the transitions among operating states for the DMA manager thread and DMA channel threads. The DMAC provides a separate state machine for each thread.

Figure 16-2: Thread Operating States

In the above figure, the DMAC permits all of the following:

- Only DMA channel threads can use states shown in blue
- Arcs with no letter designator indicate state transitions for the DMA manager and DMA channel threads, otherwise use is restricted as follows:
 - C—DMA channel threads only
 - M—DMA manager thread only
- States within the dotted line can transition to the Faulting completing, Faulting, or Killing

After the DMAC exits from reset, it sets all DMA channel threads to the Stopped state, and DMA manager thread moves to the Stopped state.

The following sections describe the *Thread Operating* states:

Stopped

The thread has an invalid PC (Program Counter) and it is not fetching instructions. Depending on the thread type, you can cause the thread to move to the Executing state by all of the following:

- DMA manager thread—Issuing the DMAGO instruction through the slave interface
- DMA channel thread—Programming the DMA manager thread to execute DMAGO for a DMA channel thread in the Stopped state

Executing

The thread has a valid PC and therefore the DMAC includes the thread when it arbitrates. The thread can then change to one of the following states under the following conditions:

- Stopped—When the DMA manager thread executes `DMAEND`
 - Cache miss—When the instruction cache does not contain the next instruction for either the DMA manager thread or the DMA channel thread
 - Updating PC—When the DMAC calculates the address of the next access in the cache
 - Waiting for event—When a thread executes `DMAWFE`
 - At barrier—When a DMA channel thread either:
 - Executes `DMARMB`, `DMAWMB`, or `DMAFLUSHP`
 - Updates control registers that affect alignment during a DMA Cycle
 - Waiting for peripheral—When a DMA channel thread executes `DMAWFP`
 - Killing—When a DMA channel thread executes `DMAKILL`
 - Faulting completing—For a DMA channel thread when either:
 - The thread executes an undefined or invalid instruction
 - An AXI error occurs during an instruction fetch or data transfer
 - Faulting—For the DMA manager thread when either:
 - The thread executes an undefined or invalid instruction
 - An AXI error occurs during an instruction fetch
- For a DMA channel thread when a watchdog timeout abort occurs.
- Completing—When a DMA channel thread executes `DMAEND`

Cache Miss

The thread is stalled and the DMAC is performing a cache line fill. After it completes the cache fill, the thread returns to the Executing state.

Updating PC

The DMAC is calculating the address of the next access in the cache. After it calculates the PC, the thread returns to the Executing state.

Waiting For Event

The thread is stalled and is waiting for the DMAC to execute `DMASEV` using the corresponding event number. After the corresponding event occurs, the thread returns to the Executing state.

At Barrier

A DMA channel thread is stalled and the DMAC is waiting for transactions on the AXI to complete. After the AXI transactions complete, the thread returns to the Executing state.

Waiting For Peripheral

A DMA channel thread is stalled and the DMAC is waiting for the peripheral to provide the requested data. After the peripheral provides the data, the thread returns to the Executing state.

Faulting Completing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Faulting state.

Faulting

The thread is stalled indefinitely. The thread moves to the Stopped state when you use the `DBGCMD` register to instruct the DMAC to execute `DMAKILL` for that thread.

Killing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Stopped state.

Completing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Stopped state.

Related Information

[Updating DMA Channel Control Registers During a DMA Cycle](#) on page 16-24

Initializing the DMAC

The DMAC provides several memory-mapped control signals that initialize its operating state when it exits from reset. The DMAC does not automatically begin executing code when it exits from reset. The system manager controls these memory-mapped control signals.

Related Information

[System Manager](#) on page 5-1

How to Set the Security State of the DMA Manager

The `boot_manager_ns` signal is the only method to set the security state of the DMA manager.

When the DMAC exits from reset, it reads the status of the `boot_manager_ns` signal and sets the security of the DMA manager.

Note: When set, the security state remains constant until a state transition on the `dma_rst_n` signal resets the DMAC.

Related Information

- [DMA Manager Thread in Secure State](#) on page 16-20
Describes how the security state of the DMA manager affects how the DMAC operates.
- [DMA Manager Thread in Non-Secure State](#) on page 16-20

How to Set the Security State for the Interrupt Outputs

The DMAC provides the `boot_irq_ns[7:0]` signals to enable you to assign each `irq[x]` signal to a security state.

The `boot_irq_ns[7:0]` signals connect to the system manager. Before taking the DMA out of reset, you should program `boot_irq_ns[7:0]` through the system manager to control which interrupt bits are secure.

Note: The DMAC samples the `boot_irq_ns[7:0]` bits immediately after reset and then ignores them until the next reset.

When set, the security state of each `irq[x]` signal remains constant until a state transition on the `dma_rst_n` signal resets the DMAC.

Related Information

[Security Usage](#) on page 16-19

Describes how the security state of the `irq[x]` signals affects how the DMAC executes the DMAWFE and DMASEV instructions.

How to Set the Security State for a Peripheral Request Interface

The DMAC provides the signals to enable you to assign each peripheral request interface to a security state.

The `boot_periph_ns[31:0]` signals connect to the system manager. Before taking the DMA out of reset, you should program the `boot_periph_ns[31:0]` signals through the system manager to control which peripheral interfaces are secure.

Note: The DMAC samples the `boot_periph_ns[31:0]` bits immediately after reset and then ignores them until the next reset. When set, the security state of each peripheral request interface remains constant until a state transition on the `dma_rst_n` signal resets the DMAC.

Related Information

[Security Usage](#) on page 16-19

Describes the effect of the security state of the peripheral request interfaces on the execution of the DMAWFP, DMALDP, DMASTP, or DMAFLUSHP instructions by a DMA channel thread.

Using the Slave Interfaces

The slave interfaces connect the DMAC to the level 4 (L4) main bus and enable the MPU to access the registers. Using these registers, the MPU can perform the following functions:

- Access the status of the DMA manager thread
- Access the status of the DMA channel threads
- Enable or clear interrupts
- Enable events
- Execute an instruction for the DMAC by programming the following debug registers:
 - DBGCMD register
 - DBGINST0 register
 - DBGINST1 register

Issuing Instructions to the DMAC using a Slave Interface

When the DMAC is operating, you can only issue the following instructions:

- `DMAGO`—Starts a DMA transaction using a DMA channel that you specify
- `DMASEV`—Signals the occurrence of an event, or interrupt, using an event number that you specify
- `DMAKILL`—Terminates a thread

You must ensure that you use the appropriate slave interface, depending on the security state in which the `boot_manager_ns` signal initializes the DMAC. For example, if the DMAC is in the Secure state, you must issue the instruction using the secure slave interface, otherwise the DMAC ignores the instruction. You can use the secure or non-secure slave interface to start or restart a DMA channel when the DMAC is in the Non-secure state.

Note: Before you can issue instructions using the debug instruction registers or the `DBGCMD` register, you must read the `DBGSTATUS` register to ensure that debug is idle, otherwise the DMAC ignores the instructions.

The DMAC immediately processes any instructions received from a slave interface, unless the pipeline is busy processing another instruction.

Note: Prior to issuing `DMAGO`, you must ensure that the system memory contains a suitable program for the DMAC to execute, starting at the address that the `DMAGO` specifies.

Using `DMAGO` with the Debug Instruction Registers

The following example shows the necessary steps to start a DMA channel thread using the debug instruction registers:

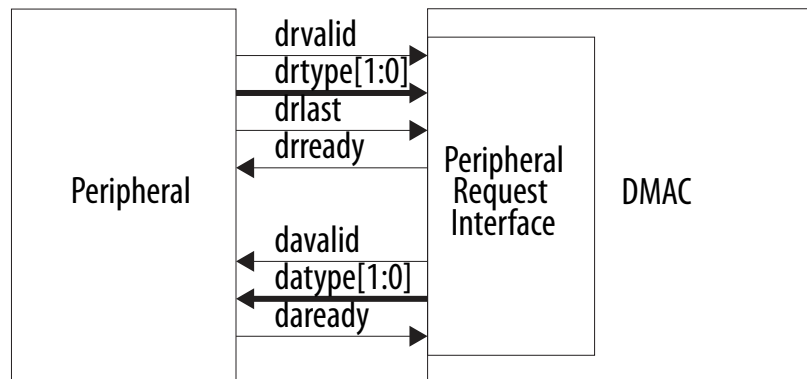

1. Create a program for the DMA channel.
2. Store the program in a region of system memory.
3. Program one of the slave interfaces on the DMAC to a `DMAGO` instruction as follows:
 - a. Poll the `DBGSTATUS` register to ensure that debug is idle, and the `dbgstatus` bit is 0.
 - b. Write to the `DBGINST0` register and enter all of the following:
 - Instruction byte 0 encoding for `DMAGO`
 - Instruction byte 1 encoding for `DMAGO`
 - Debug thread bit to 0 to select the DMA manager thread
 - c. Write to the `DBGINST1` register with the `DMAGO` instruction byte [5:2] data. You must set these four bytes to the address of the first instruction in the program that is written to system memory in [step 2](#) above.
4. Instruct the DMAC to execute the instruction that the debug instruction registers contain by writing zero to the `DBGCMD` register. The DMAC starts the DMA channel thread and sets the `dbgstatus` bit to 1. After the DMAC completes execution of the instruction, it clears the `dbgstatus` bit to 0.

Peripheral Request Interface

The following figure shows that the peripheral request interface consists of a peripheral request bus and a DMAC acknowledge bus that use the prefixes:

- `dr`—The peripheral request bus
- `da`—The DMAC acknowledge bus

Figure 16-3: Request and Acknowledge Buses on the Peripheral Request Interface

The peripheral indicates the following on the request bus:

- Request a single transfer
- Request a burst transfer
- Acknowledge a flush request

The peripheral indicates the DMAC when it issues the last request of the DMA transfer sequence.

The DMAC can indicate the following on the acknowledge bus:

- When it completes the requested single transfer
- When it completes the requested burst transfer
- When it issues a flush request

You can assign a peripheral request interface to any of the DMA channels. When a DMA channel thread executes `DMAWFP`, the value programmed in the peripheral [4:0] field specifies the peripheral associated with that DMA channel.

The DMAC supports 32 peripheral request handshakes. Each request handshake can receive up to four outstanding requests, and is assigned a specific peripheral device ID. The following table lists the peripheral device ID assignments.

Table 16-1: Peripheral Request Interface Mapping

Peripheral	Request Interface ID	Protocol

UART 1 Tx	30	Synopsys
UART 1 Rx	31	Synopsys

Request Acceptance Capability

The DMAC can accept one active request for each peripheral request interface. An active request exists when the DMAC has not started the requested AXI data transfers.

Peripheral Length Management

A peripheral can control the quantity of data that a DMA cycle contains, without the DMAC being aware of how many data transfers it contains. The peripheral controls the DMA cycle in one of the following ways:

- Selects a single transfer
- Selects a burst transfer
- Notifies the DMAC when it commences the final request in the current series

When the DMAC executes a `DMAWFP` peripheral instruction, it halts execution of the thread and waits for the peripheral to send a request. When the peripheral sends the request, the DMAC sets the request flags depending on the state of the following signals:

- `drtype_<x>[1:0]` —The DMAC sets the state of the `request_type` flag:
 - `drtype_<x>[1:0]=b00`—`request_type <x> = Single`
 - `drtype_<x>[1:0]=b01`—`request_type <x> = Burst`
- `drlast_<x>`—The DMAC sets the state of the `request_last` flag:
 - `drlast_<x>=0`—`request_last <x> = 0`
 - `drlast_<x>=1`—`request_last <x> = 1`

Note: If the DMAC executes a `DMAWFP` single or `DMAWFP` burst instruction then the DMAC sets:

- The `request_type<x>` flag to Single or Burst, respectively
- The `request_last<x>` flag to 0

`DMALPFE` is an assembler directive that forces the associated `DMALPEND` instruction to have its `nf` bit cleared, creating a program loop that does not use a loop counter to terminate the loop.

The DMAC exits the loop when the `request_last` flag is set.

The DMAC conditionally executes the following instructions, depending on the state of the `request_type` and `request_last` flags:

- **DMALD**, **DMAST**, **DMALPEND** - When these instructions use the optional B|S suffix then the DMAC executes a `DMANOP` if the `request_type` flag does not match.
- **DMALDP<B|S>**, **DMASTP<B|S>** - The DMAC executes a `DMANOP` if the `request_type <x>` flag does not match the B|S.
- **DMALPEND** - When the `nf` bit is 0, the DMAC executes a `DMANOP` if the `request_last` flag is set.

Use the `DMALDB`, `DMALDPB`, `DMASTB` and `DMASTPB` instructions if you require the DMAC to issue a burst transfer when the DMAC receives a burst request. The values in the `CCRn` register control the amount of data that the DMAC transfers.

Use the `DMALDS`, `DMALDPS`, `DMASTS` and `DMASTPS` instructions if you require the DMAC to issue a single transfer when the DMAC receives a single request. The DMAC ignores the value of the `src_burst_len` and `dst_burst_len` fields in the `CCRn` register and sets the `arlen[3:0]` or `awlen[3:0]` buses to 0x0.

DMAC Length Management

The DMAC controls the total amount of data. The peripheral uses the peripheral request interface to notify the DMAC when it requires the DMAC to transfer data to or from the peripheral. The DMA channel thread controls how the DMAC responds to the peripheral requests.

The following constraints apply to DMAC length management:

- The total quantity of data for all the single requests from a peripheral must be less than the quantity of data for a burst request for that peripheral.

Note: The `CCRn` register controls how much data is transferred for a burst request and a single request. Altera recommends that you do not update a `CCRn` register when a transfer is in progress for channel `n`.

- After the peripheral sends a burst request, the peripheral must not send a single request until the DMAC acknowledges that the burst request is complete.

Program the `DMAWFP` single instruction when you require the program thread to halt execution until the peripheral request interface receives any request type.

- Single— If the head entry in the request FIFO buffer is a single request type, the DMAC pops the entry from the FIFO buffer and continues program execution.
- Burst— If the head entry in the request FIFO buffer is a burst request type, the DMAC leaves the entry in the FIFO buffer and continues program execution.

Note: The burst request entry remains in the request FIFO buffer until the DMAC executes a `DMAWFP` burst instruction or a `DMAFLUSHP` instruction.

Program the `DMAWFP` burst instruction when you require the program thread to halt execution until the peripheral request interface receives a burst request.

- Single— If the head entry in the request FIFO buffer is a single request type, the DMAC removes the entry from the FIFO buffer and continues program execution.
- Burst— If the head entry in the request FIFO buffer is a burst request type, the DMAC pops the entry from the FIFO buffer and continues program execution.

Program the `DMALDP` instruction when you require the DMAC to send an acknowledgment to the peripheral when it completes the AXI read transfers. Similarly, use the `DMASTP` instruction when you require the DMAC to send an acknowledgment to the peripheral when it completes the AXI write transfers. The DMAC uses the acknowledge bus to signal a transfer acknowledgment to the peripheral.

Note: The DMAC sends an acknowledgment for a read transaction when the `rvalid` and `rlast` signals are high and for a write transaction when `bvalid` signal is high. The DMAC might send an acknowledgment to the peripheral while the transfer of write data to the end destination is still in progress.

Use the `DMAFLUSHP` instruction to reset the request FIFO buffer for the peripheral request interface. After the DMAC executes `DMAFLUSHP`, it ignores peripheral requests until the peripheral acknowledges the flush request. This protocol enables the DMAC and peripheral to synchronize with each other.

ARM Protocol

The DMA peripheral request interface communicates with peripherals by either the ARM protocol or the Synopsys protocol.

For peripherals using the ARM protocol, clock-crossing logic is the only logic between the DMA and the peripheral.

Synopsys Protocol Overview

The Synopsys protocol is used for the hardware flow control that is not the same as the ARM® protocol used by the DMA-330 core.

For peripherals using the Synopsys protocol, clock-crossing logic and protocol adaptation logic exist between the DMA and the peripheral.

The Synopsys protocol is described, below:

- A single transfer line is asserted when the peripheral requests a single data transfer.
- A burst transfer line is asserted when the peripheral requests a burst transfer.

Note: The burst transfer size must be identically set in both the DMA and peripheral to avoid potential data loss or corruption.

- The single and burst transfer lines must remain asserted until the DMA issues an acknowledge back to the peripheral.

Note: If the peripheral must be reset, then the DMA should be instructed to flush the request which is translated into an acknowledge by the Synopsys protocol adapter.

- When a transfer is acknowledged, the peripheral must deassert the burst and single request lines for the duration of the acknowledgment.

Note: A transmit or receive request is not complete until the DMA issues an acknowledge back to the peripheral.

Using Events and Interrupts

The DMAC can support eight events and interrupts. The `INTEN` register determines whether each event-interrupt resource is an event or an interrupt.

When the DMAC executes a `DMASEV` instruction, it modifies the event-interrupt resource that you specify. The `INTEN` register sets the event-interrupt resource to function as an:

- **Event**—The DMAC generates an event for the specified event-interrupt resource. When the DMAC executes a `DMAWFE` instruction for the same event-interrupt resource then it clears the event.
- **Interrupt**—The DMAC sets the `irq <event_num>` signal high, where `<event_num>` is the number of the specified event resource. To clear the interrupt you must write to the `INTCLR` register.

Using an Event to Restart DMA Channels

When you program the `INTEN` register to generate an event, you can use the `DMASEV` and `DMAWFE` instructions to restart one or more DMA channels.

DMAC executes `DMAWFE` before `DMASEV`

To restart a single DMA channel:

1. The first DMA channel executes `DMAWFE` and then stalls while it waits for the event to occur.
2. The other DMA channel executes `DMASEV` using the same event number generating an event and restarting the first DMA channel. The DMAC clears the event, one clock cycle after it executes `DMASEV`.

You can program multiple channels to wait for the same event. For example, if four DMA channels have all executed `DMAWFE` for event 2, and another DMA channel executes `DMASEV` for event 2, the four DMA channels all restart at the same time. The DMAC clears the event, one clock cycle after it executes `DMASEV`.

DMAC executes `DMASEV` before `DMAWFE`

If the DMAC executes `DMASEV` before another channel executes `DMAWFE`, the event remains pending until the DMAC executes `DMAWFE`. When the DMAC executes `DMAWFE`, it halts execution for one `ac1k` clock cycle, clears the event and then continues execution of the channel thread.

For example, if the DMAC executes `DMASEV 6` and none of the other threads have executed `DMAWFE 6`, then the event remains pending. If the DMAC executes the `DMAWFE 6` instruction for channel 4 and then executes the `DMAWFE 6` instruction for channel 3, the following actions occur:

1. The DMAC halts execution of the channel 4 thread for one clock cycle.
2. The DMAC clears event 6.
3. The DMAC resumes execution of the channel 4 thread.
4. The DMAC halts execution of the channel 3 thread and the thread stalls while it waits for the next occurrence of event 6.

Interrupting the MPU Subsystem

The DMAC provides the `irq[x]` signals for use as active-high level-sensitive interrupts to the MPU subsystem. When you program the `INTEN` register to generate an interrupt, after the DMAC executes `DMASEV`, it sets the corresponding `irq[x]` signal high.

The MPU subsystem can clear the interrupt by writing to the `INTCLR` register.

Note: Executing `DMAWFE` does not clear an interrupt.

If you use the `DMASEV` instruction to notify a microprocessor when the DMAC completes a `DMALD` or `DMAST` instruction then you should insert a memory barrier instruction before the `DMASEV`. Otherwise the DMAC might signal an interrupt before the AXI transfers complete.

The following program shows the example of Memory Barrier Instruction.

```
DMALD
DMAST
# Issue a write memory barrier
# Wait for the AXI write transfer to complete before the DMAC
# can send an interrupt
DMAWMB
# The DMAC sends the interrupt
DMASEV
```

Aborts

Abort Types

An abort can be classified as either precise or imprecise, depending on whether the DMAC provides an abort handler with the precise state of the DMAC when the abort occurs.

- Precise Abort - The DMAC updates the PC register with the address of the instruction that created the abort.
- Imprecise Abort - The PC register might contain the address of an instruction that did not cause the abort to occur.

Abort Sources

The DMAC indicates a precise abort under any of the following conditions:

- A DMA channel thread in the Non-secure state attempts to program its CCRn register and generate a secure AXI transaction.
- A DMA channel thread in the Non-secure state executes DMAWFE or DMASEV for an event that is set as secure. The `boot_irq_ns` memory-mapped control signals initialize the security state for an event.

Note: For each event, the `INTEN` register controls if the DMAC generates an event or signals an interrupt.

- A DMA channel thread attempts to execute `DMAST` but the DMAC calculates that when it eventually performs the store, the MFIFO buffer contains insufficient data to enable it to complete the store.
- A DMA channel thread in the Non-secure state executes `DMAWFP`, `DMALDP`, `DMASTP`, or `DMAFLUSHP` for a peripheral request interface that is set as secure. The `boot_periph_ns` memory-mapped control signals initialize the security state for a peripheral request interface.
- A DMA manager thread in the Non-secure state executes `DMAGO` to attempt to start a secure DMA channel thread.
- The DMAC receives an ERROR response on the AXI master interface when it performs an instruction fetch.
- A thread executes an undefined instruction.
- A thread executes an instruction with an operand that is invalid for the configuration of the DMAC.

Note: When the DMAC signals a precise abort, the instruction that triggers the abort is not executed. Instead, the DMAC executes a `DMANOP`.

The DMAC signals an imprecise abort under the following conditions:

- The DMAC receives an ERROR response on the AXI master interface when it performs a data load.
- The DMAC receives an ERROR response on the AXI master interface when it performs a data store.
- A DMA channel thread executes `DMALD` or `DMAST`, and the MFIFO buffer is too small to hold the required amount of data.
- A DMA channel thread executes `DMAST` but the thread has not executed sufficient `DMALD` instructions.
- A DMA channel thread locks up because of resource starvation, and this causes the internal watchdog timer to time out.

Watchdog Abort

The DMAC can lock up if one or more DMA channel programs are running and the MFIFO buffer is too small to satisfy the storage requirements of the DMA programs.

The DMAC contains logic to prevent it from remaining in a state where it is unable to complete a DMA transfer.

The DMAC detects a lock up when all of the following conditions occur:

- Load queue is empty.
- Store queue is empty.
- All of the running channels are prevented from executing a `DMALD` instruction either because the MFIFO buffer does not have sufficient free space or another channel owns the load-lock.

When the DMAC detects a lockup, it signals an interrupt and can also abort the contributing channels. The DMAC behavior depends on the state of the `wd_irq_only` bit in the `WD` register, if:

- `wd_irq_only=0`—The DMAC aborts all of the contributing DMA channels and sets the `irq_abort` signal high.
- `wd_irq_only=1`—The DMAC sets the `irq_abort` signal high.

Related Information

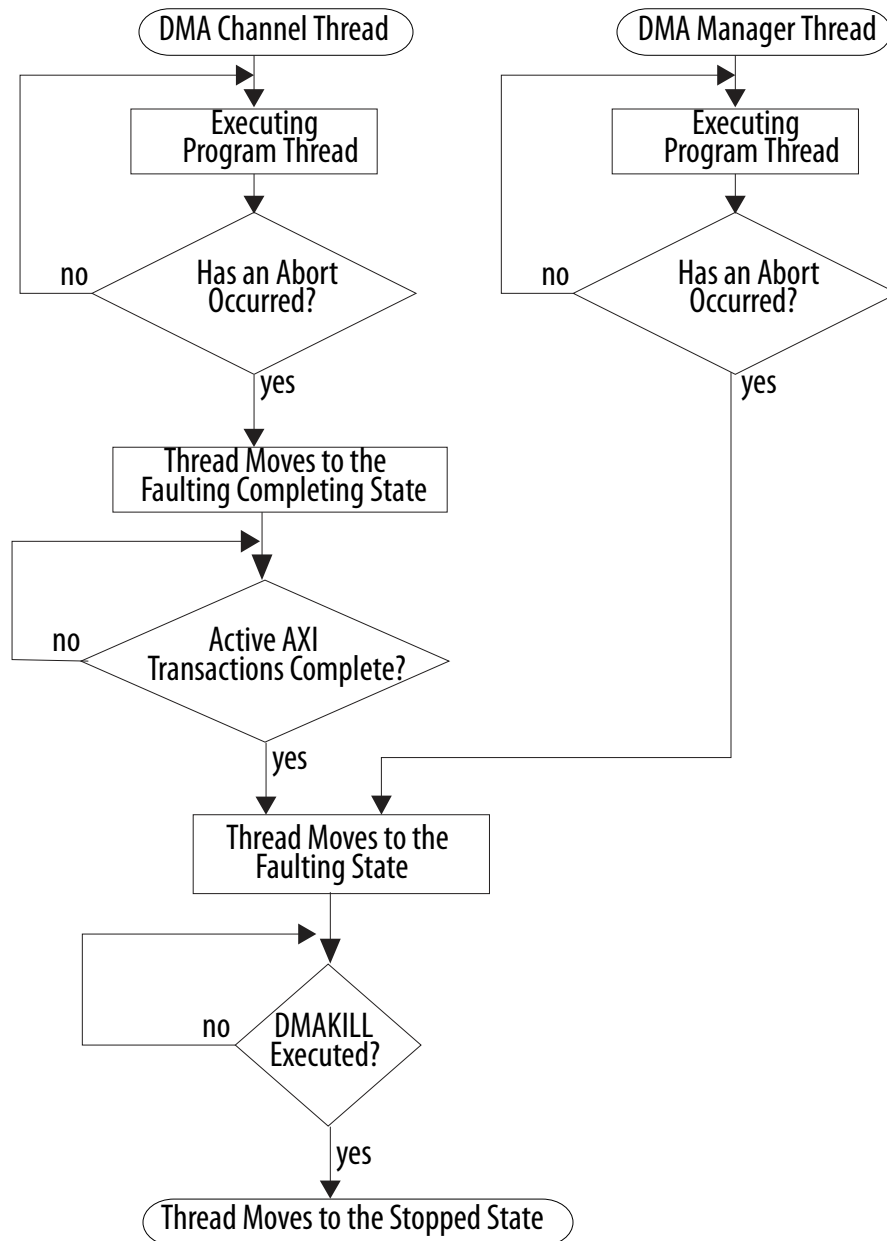

[Resource Sharing Between DMA Channels](#) on page 16-24

Abort Handling

The architecture of the DMAC is not designed to recover from an abort. You must use an external agent, such as the MPU, to terminate a thread when an abort occurs.

The following figure shows the operating states for the DMA channel and DMA manager threads after an abort occurs.

Figure 16-4: Abort Process

After an abort occurs, the action of the DMAC depends on the thread type:

- DMA channel thread—The thread immediately moves to the Faulting completing state. In this state, the DMAC performs the following operations:
 - Sets the `irq_abort` signal high.
 - Stops executing instructions for the DMA channel.
 - Invalidates all cache entries for the DMA channel updates the `CPCn` register to contain the address of the aborted instruction provided that the abort is precise.
 - Does not generate AXI accesses for any instructions remaining in the read queue and write queue.
 - Permits currently active AXI transactions to complete.

Note: After the transactions for the DMA channel finish, the thread moves to the Faulting state.

- DMA manager thread—The thread immediately moves to the Faulting state and the DMAC sets the `irq_abort` signal high.

The external agent can respond to the assertion of the `irq_abort` signal by all of the following:

- Reading the status of the `FSRD` register to determine if the DMA manager is Faulting. In the Faulting state, the `FSRD` register provides the cause of the abort.
- Reading the status of the `FSRC` register to determine if a DMA channel is Faulting. In the Faulting state, the `FSRC` register provides the cause of the abort.

To enable a thread in the Faulting state to move to the Stopped state, the external agent must:

- Program the `DBGINST0` register with the encoding for the `DMAKILL` instruction.
- Write to the `DBGCMD` register.

Note: If the aborted thread is secure, you must use the secure slave interface to update these registers.

After a thread in the Faulting state executes `DMAKILL`, it moves to the Stopped state.

Security Usage

When the DMAC exits from reset, the status of the configuration signals configures the security for:

- DMA manager thread—The `DNS` bit in the `DSR` register returns the security state of the DMA manager thread.
- Events and interrupts—The `INS` bit in the `CR3` register returns the security state of the event-interrupt resources.
- Peripheral request interfaces—The `PNS` bit in the `CR4` register returns the security state of these interfaces.

Additionally, each DMA channel thread contains a dynamic non-secure bit, `CNS`, that is valid when the channel is not in the Stopped state.

DMA Manager Thread in Secure State

If the `DNS` bit is 0, the DMA manager thread operates in the Secure state and performs only secure instruction fetches. When a DMA manager thread in the Secure state processes:

- `DMAGO`—The DMAC uses the status of the `ns` bit, to set the security state of the DMA channel thread by writing to the `CNS` bit for that channel.
- `DMAWFE`—The DMAC halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding `INS` bit.
- `DMASEV`—The DMAC sets the corresponding bit in the `INT_EVENT_RIS` register, irrespective of the security state of the corresponding `INS` bit.

DMA Manager Thread in Non-Secure State

If the `DNS` bit is 1, the DMA manager thread operates in the Non-secure state, and it only performs non-secure instruction fetches. When a DMA manager thread in the Non-secure state processes:

`DMAGO` - The DMAC uses the status of the `ns` bit to control if it starts a DMA channel thread.

- If `ns = 0`, then the DMAC does not start a DMA channel thread and instead it:
 - Executes an `NOP`
 - Sets the `FSRD` register
 - Sets the `dmago_err` bit in the `FTRD` register
 - Moves the DMA manager to the Faulting state
- If `ns = 1`, then the DMAC starts a DMA channel thread in the non-secure state and programs the `CNS` bit to be non-secure.

`DMAWFE` - The DMAC uses the status of the corresponding `INS` bit in the `CR3` register to control whether it waits for the event.

- If `INS = 0`, then the event is in the secure state. The DMAC:
 - Executes an `NOP`
 - Sets the `FSRD` register
 - Sets the `mgr_evnt_err` bit in the `FTRD` register
 - Moves the DMA manager to the Faulting state
- If `INS = 1`, then the event is in the non-secure state. The DMAC halts execution of the thread and waits for the event to occur.

`DMASEV` - The DMAC uses the status of the corresponding `INS` bit in the `CR3` register to control if it creates the event interrupt.

- If `INS = 0`, then the event-interrupt resource is in the Secure state. The DMAC:
 - Executes a `NOP`
 - Sets the `FSRD` register
 - Sets the `mgr_evnt_err` bit in the `FTRD` register
 - Moves the DMA manager to the Faulting state
- If `INS = 1`, then the event-interrupt resource is in the non-secure state. The DMAC creates the event interrupt.

DMA Channel Thread in Secure State

When the `CNS` bit is 0, the DMA channel thread is programmed to operate in the secure state and to only perform secure instruction fetches.

When a DMA channel thread in the secure state processes the following instructions:

- `DMAWFE` - The DMAC halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, regardless of the security state of the corresponding `INS` bit in the `CR3` register.
- `DMASEV` - The DMAC creates the event interrupt, regardless of the security state of the corresponding `INS` bit in the `CR3` register.
- `DMAWFP` - The DMAC halts execution of the thread until the peripheral signals a DMA request at which point the DMAC continues execution of the thread, regardless of the security state of the corresponding `PNS` bit in the `CR4` register.
- `DMALDP` and `DMASTP` - The DMAC sends a message to the peripheral to communicate that data transfer is complete, regardless of the security state of the corresponding `PNS` bit in the `CR4` register.
- `DMAFLUSHP` - The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status, regardless of the security state of the corresponding `PNS` bit in the `CR4` register.

When a DMA channel thread is in the Secure state, it enables the DMAC to perform secure and non-secure AXI accesses.

DMA Channel Thread in Non-Secure State

When the `CNS` bit is 1, the DMA channel thread is programmed to operate in the non-secure state and to only perform non-secure instruction fetches.

When a DMA channel thread in the Non-secure state processes the following instructions:

- **DMAWFE** - The DMAC uses the status of the corresponding **INS** bit in the **CR3** register, to control if it waits for the event.
 - If **INS** =0, then the event is in the Secure state. The DMAC:
 - Executes an **NOP**
 - Sets the appropriate bit in the **FSRC** register corresponding to the DMA channel number
 - Sets the **ch_evnt_err** bit in the **FTRn** register
 - Moves the DMA channel to the Faulting completing state
 - If **INS** =1, then the event is in the Non-secure state. The DMAC halts execution of the thread and waits for the event to occur.
- **DMASEV** - The DMAC uses the status of the corresponding **INS** bit in the **CR3** register, to control if it creates the event.
 - If **INS** =0, then the event-interrupt resource is in the Secure state. The DMAC:
 - Executes an **NOP**
 - Sets the appropriate bit in the **FSRC** register corresponding to the DMA channel number
 - Sets the **ch_evnt_err** bit in the **FTRn** register
 - Moves the DMA channel to the Faulting completing state
 - If **INS** =1, then the event-interrupt resource is in the Non-secure state. The DMAC creates the event interrupt.
- **DMAWFP** - The DMAC uses the status of the corresponding **PNS** bit in the **CR4** register, to control if it waits for the peripheral to signal a request.
 - If **PNS** =0, then the peripheral is in the Secure state. The DMAC:
 - Executes an **NOP**
 - Sets the appropriate bit in the **FSRC** register corresponding to the DMA channel number
 - Sets the **ch_periph_err** bit in the **FTRn** register
 - Moves the DMA channel to the Faulting completing state
 - If **PNS** =1, then the peripheral is in the Non-secure state. The DMAC halts execution of the thread and waits for the peripheral to signal a request.
- **DMALDP** and **DMASTP** - The DMAC uses the status of the corresponding **PNS** bit in the **CR4** register, to control if it sends an acknowledgement to the peripheral.
 - If **PNS** =0, then the peripheral is in the Secure state. The DMAC:
 - Executes an **NOP**
 - Sets the appropriate bit in the **FSRC** register corresponding to the DMA channel number
 - Sets the **ch_periph_err** bit in the **FTRn** register
 - Moves the DMA channel to the Faulting completing state
 - If **PNS** =1, then the peripheral is in the Non-secure state. The DMAC sends a message to the peripheral to communicate when the data transfer is complete.
- **DMAFLUSHP** - The DMAC uses the status of the corresponding **PNS** bit in the **CR4** register, to control if it sends a flush request to the peripheral.
 - If **PNS** =0, then the peripheral is in the Secure state. The DMAC:
 - Executes an **NOP**
 - Sets the appropriate bit in the **FSRC** register corresponding to the DMA channel number
 - Sets the **ch_periph_err** bit in the **FTRn** register
 - If **PNS** =1, then the peripheral is in the non-secure state. The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status.

When a DMA channel thread is in the non-secure state, and a `DMAMOV` `CCR` instruction attempts to program the channel to perform a secure AXI transaction, the DMAC:

1. Executes a `DMANOP`
2. Sets the appropriate bit in the `FSRC` register corresponding to the DMA channel number
3. Sets the `ch_rdwr_err` bit in the `FTRn` register
4. Moves the DMA channel thread to the Faulting completing state

Programming Restrictions

Certain restrictions apply when programming the DMAC.

Fixed Unaligned Bursts

The DMAC does not support fixed unaligned bursts. The DMAC treats the following conditions as programming errors:

- **Unaligned read**
 - `src_inc` field is 0 in the `CCRn` register.
 - The `SARn` register contains an address that is not aligned to the size of data that the `src_burst_size` field contains.
- **Unaligned write**
 - `dst_inc` field is 0 in the `CCRn` register.
 - The `DARn` register contains an address that is not aligned to the size of data that the `dst_burst_size` field contains.

Endian Swap Size Restrictions

If you program the `endian_swap_size` field in the `CCRn` register, to enable a DMA channel to perform an endian swap, then you must set the corresponding `SAR` register and the corresponding `DARn` register to contain an address that is aligned to the size that the `endian_swap_size` field specifies before executing any `DMALD` or `DMAST` instructions.

Note: If you update any of `endian_swap_size`, `SARn`, or `DARn`, for example, using a `DMAADDH SAR` instruction, then you must ensure that the `SARn` and `DARn` registers contain an address aligned to the size that the `endian_swap_size` field specifies before executing any additional `DMALD` or `DMAST` instructions.

If you program the `src_inc` field in the `CCR` register to use a fixed address, you must program the `src_burst_size` field to select a burst size that is greater than or equal to the value that the `endian_swap_size` field specifies. Similarly, if you program the `dst_inc` field to select a fixed destination address, you must program the `dst_burst_size` field to select a burst size that is greater than or equal to the value that the `endian_swap_size` field specifies.

If you program the `dst_inc` field in the `CCRn` register to use an incrementing address, you must program the `CCRn` register so that `dst_burst_len` times `dst_burst_size` is a multiple of `endian_swap_size`. For example, if `endian_swap_size` = 2, 32-bit, and `dst_burst_size` = 1, 2 bytes per beat, then you can program `dst_burst_len` = 1, 3, 5, ..., 15, that is 2, 4, 6, ..., 16 transfers.

Updating DMA Channel Control Registers During a DMA Cycle

Prior to the DMAC executing a sequence of `DMALD` and `DMAST` instructions, the values you program in to the `CCRN` register, `SARN` register, and `DARN` register control the data byte lane manipulation that the DMAC performs when it transfers the data from the source address to the destination address.

You can update these registers during a DMA cycle, but if you change certain register fields, then the DMAC may discard data. The following sections describe the register fields that could have a detrimental impact on a data transfer.

Updates that affect the destination address

If you use a `DMAMOV` instruction to update the `DARN` register or `CCRN` register part way through a DMA cycle, then there may be a discontinuity in the destination data stream.

A discontinuity occurs if you change any of the following:

- `endian_swap_size` field.
- `dst_inc` bit.
- `dst_burst_size` field when `dst_inc = 0`, that is, fixed-address burst.
- `DARN` register so that it modifies the destination byte lane alignment. Because the bus width is 64 bits, you change bits [2:0] in the `DARN` register.

When a discontinuity in the destination data stream occurs, the DMAC:

1. Halts execution of the DMA channel thread.
2. Completes all outstanding read and write operations for the channel. That is, as if the DMAC were executing `DMARMB` and `DMAWMB`.
3. Discards any residual MFIFO buffer data for the channel.
4. Resumes execution of the DMA channel thread.

Updates that affect the source address

If you use a `DMAMOV` instruction to update the `SARN` register or `CCRN` register part way through a DMA cycle then this might cause a discontinuity in the source data stream.

A discontinuity occurs if you change any of the following:

- `src_inc` bit.
- `src_burst_size` field.
- `SAR` register so that it modifies the source byte lane alignment. Because the bus width is 64 bits, you change bits [2:0] in the `SAR` register.

When a discontinuity in the source data stream occurs, the DMAC:

1. Halts execution of the DMA channel thread.
2. Completes all outstanding read operations for the channel. That is, as if the DMAC were executing `DMARMB`.
3. Resumes execution of the DMA channel thread. No data is discarded from the MFIFO buffer.

Resource Sharing Between DMA Channels

DMA channel programs share the MFIFO buffer data storage resource. You must not start a set of concurrently running DMA channel programs with a resource requirement that exceeds 512, the size of

the MFIFO buffer. If you exceed this limit then the DMAC might lock up and generate a Watchdog abort, refer to “Watchdog Abort”.

The DMAC includes a mechanism called the *load lock* to ensure that the shared MFIFO buffer resource is used correctly. The load-lock is either owned by one channel or it is free. The channel that owns the load-lock can execute `DMALD` instructions successfully. A channel that does not own the load-lock pauses at a `DMALD` instruction until it takes ownership of the load-lock.

A channel claims ownership of the load lock when:

- It executes a `DMALD` or `DMALDP` instruction
- No other channel currently owns the load-lock.

A channel releases ownership of the load-lock when any of the following occur:

- It executes a `DMAST`, `DMASTP`, or `DMASTZ`
- It reaches a barrier, that is, it executes `DMARMB` or `DMAWMB`
- It waits, that is, it executes `DMAWFP` or `DMAWFE`
- It terminates normally, that is, it executes `DMAEND`
- It aborts for any reason, including `DMAKILL`.

The MFIFO buffer resource usage of a DMA channel program is measured in MFIFO buffer entries, and rises and falls as the program proceeds. The MFIFO buffer resource requirement of a DMA channel program is described using a *static requirement* and a *dynamic requirement* which are affected by the load-lock mechanism.

The static requirement is defined to be the maximum number of MFIFO buffer entries that a channel is currently using before that channel does one of the following:

- Executes a `WFP` or `WFE` instruction
- Claims ownership of the load-lock.

The dynamic requirement is defined to be the difference between the static requirement and the maximum number of MFIFO buffer entries that a channel program uses at any time during its

To calculate the total MFIFO buffer requirement, add the largest dynamic requirement to the sum of all the static requirements.

To avoid DMAC lockup, the total MFIFO buffer requirement of the set of channel programs must be equal to or less than 512, the MFIFO buffer depth.

Clocks and Resets

Clock

The DMA controller operates on the `l4_main_clk` input.

Related Information

[Clock Manager](#) on page 2-1

Resets

The DMA controller has nine reset signals. The reset manager drives `dma_rst_n` signal to the DMA controller on a cold or warm reset. The reset manager drives the `dma_periph_if_rst_n[7:0]` signals to reset the eight FPGA PRIs.

Table 16-2: Reset inputs to the DMA controller

Reset Signal	Description
<code>dma_rst_n</code>	Resets DMA controller
<code>dma_periph_if_rst_n[7:0]</code>	Resets the eight FPGA peripheral request interfaces

Related Information

[Reset Manager](#) on page 3-1

Taking the DMA Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

[Reset Manager](#) on page 3-1

Constraints and Limitations of Use

DMA Channel Arbitration

The DMAC uses a round-robin scheme to serve the active DMA channels. To ensure that the DMAC continues to serve the DMA manager, it always serves the DMA manager prior to serving the next DMA channel.

Note: You cannot alter the arbitration process of the DMAC.

DMA Channel Prioritization

The DMAC responds to all active DMA channels with equal priority. You cannot increase the priority of a DMA channel over any other DMA channels.

Instruction Cache Latency

When a cache miss occurs, most of the delay is introduced by the memory containing the DMA code; the DMAC adds minimal delay.

AXI Data Transfer Size

The DMAC can only perform data accesses up to 64 bits in width. If you program the `src_burst_size` or `dst_burst_size` fields to be larger, the DMAC indicates a precise abort.

Related Information

[Abort Sources](#) on page 16-16

AXI Bursts Crossing 4 KB Boundaries

The AXI specification does not permit AXI bursts to cross 4 KB address boundaries. If you program the DMAC with a combination of burst start address, size, and length that would cause a single burst to cross a 4 KB address boundary, then the DMAC generates a pair of bursts with a combined length equal to that specified. This operation is transparent to the DMAC channel thread program so that, for example, the DMAC responds to a single `DMALD` instruction by generating the appropriate pair of AXI read bursts.

AXI Burst Types

You can program the DMAC to generate only fixed-address or incrementing-address burst types for data accesses. It does not generate wrapping-address bursts for data accesses or for instruction fetches.

AXI Write Addresses

The DMAC can issue up to eight outstanding write addresses. The DMAC does not issue a write address until it has read in all of the data bytes required to fulfill that write transaction.

AXI Write Data Interleaving

The DMAC does not generate interleaved write data. All write data beats for one write transaction are output before any write data beat for the next write transaction.

DMA Controller Programming Model

Instruction Syntax Conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

- `< >` - Any item bracketed by `<` and `>` is mandatory. A description of the item and of how it is encoded in the instruction is supplied by subsequent text.
- `[]` - Any item bracketed by `[` and `]` is optional. A description of the item and of how its presence or absence is encoded in the instruction is supplied by subsequent text.
- `" "` (spaces) - To separate items, single spaces are used for clarity. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

Instruction Set Summary

The DMAC instructions:

- Indicate a DMA prefix, to provide a unique name-space
- Have 8-bit opcodes that might use a variable data payload of 0, 8, 16, or 32 bits
- Indicate suffixes that are consistent.

Table 16-3: Instruction Syntax Summary

Mnemonic	Instruction	DMA Manager Usage	DMA Channel Usage	Description
DMAADDH	Add Halfword	No	Yes	DMAADDH on page 16-29

Mnemonic	Instruction	DMA Manager Usage	DMA Channel Usage	Description
DMAADNH	Add Negative Halfword	No	Yes	DMAADNH on page 16-29

Instructions

DMAADDH

Add Halfword adds an immediate 16-bit value to the SAR_n register or DAR_n register, for the DMA channel thread. This enables the DMAC to support two-dimensional DMA operations.

Note: The immediate unsigned 16-bit value is zero-extended before the DMAC adds it to the address, using 32-bit addition. The DMAC discards the carry bit so that addresses wrap from 0xFFFFFFFF to 0x00000000.

Figure 16-5: DMAADDH Instruction Encoding

Assembler syntax

DMAADDH <address_register>, <16-bit bit immediate>

where:

<address_register> Selects the address register to use. It must be either:

- SAR SAR_n register and sets ra to 0
- DAR DAR_n register and sets ra to 1

<16-bit immediate> The immediate value to be added to the <address_register>.

Operation

You can only use this instruction in a DMA channel thread.

DMAADNH

Add Negative Halfword adds an immediate negative 16-bit value to the SAR_n register or DAR_n register, for the DMA channel thread. This enables the DMAC to support two-dimensional DMA operations, or reading or writing an area of memory in a different order to naturally incrementing addresses.

Note: The immediate unsigned 16-bit value is one-extended to 32 bits, to create a value that is the two's complement representation of a negative number between -65536 and -1, before the DMAC adds it to the address using 32-bit addition. The DMAC discards the carry bit so that addresses wrap from

0xFFFFFFFF to 0x00000000. The net effect is to subtract between 65536 and 1 from the current value in the source or destination address register.

Figure 16-6: DMAADNH Encoding

Assembler syntax

DMAADNH <address_register>, <16-bit immediate>

where:

<address_register> Selects the address register to use. It must be either:

SAR SAR_n register and sets ra to 0

DAR DAR_n register and sets ra to 1

<16-bit immediate> The immediate value to be added to the <address_register>.

Note: You should specify the 16-bit immediate as the number that is to be represented in the instruction encoding. For example, DMAADNH DAR, 0xFFFF0 causes the value 0xFFFFFFFF0 to be added to the current value of the Destination Address register, effectively subtracting 16 from the DAR.

Operation

You can only use this instruction in a DMA channel thread.

DMAEND

End signals to the DMAC that the DMA sequence is complete. After all DMA transfers are complete for the DMA channel, the DMAC moves the channel to the Stopped state. It also flushes data from the MFIFO buffer and invalidates all cache entries for the thread.

Figure 16-7: DMAEND Instruction Encoding

Assembler syntax

DMAEND

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

DMAFLUSHP

Flush Peripheral clears the state in the DMAC that describes the contents of the peripheral and sends a message to the peripheral to resend its level status.

Figure 16-8: DMAFLUSHP Instruction Encoding

Assembler syntax

DMAFLUSHP <peripheral>

where:

<peripheral> 5-bit immediate, value 0-31

Operation

You can only use this instruction in a DMA channel thread.

DMAGO

When the DMA manager executes Go for a DMA channel that is in the Stopped state, it performs the following steps on the DMA channel:

1. Moves a 32-bit immediate into the program counter
2. Sets its security state
3. Updates it to the Executing state.

Note: If a DMA channel is not in the Stopped state when the DMA manager executes DMAGO then the DMAC does not execute DMAGO but instead it executes DMANOP.

Figure 16-9: DMAGO Instruction Encoding

Assembler syntax

DMAGO <channel_number>, <32-bit_immediate> [, ns]

where:

<channel_number> **Selects a DMA channel. It must be one of:**

- c0 DMA channel 0
- c1 DMA channel 1
- c2 DMA channel 2

c3 DMA channel 3
 c4 DMA channel 4
 c5 DMA channel 5
 c6 DMA channel 6
 c7 DMA channel 7

Note: If you provide a channel number that is not available for your configuration of the DMAC, the DMA manager thread aborts.

<32-bit_immediate> The immediate value that is written to the CPC_n register for the selected <channel_number>.

[ns]

- If ns is present, the DMA channel operates in the Non-secure state.
- Otherwise, the execution of the instruction depends on the security state of the DMA manager:

DMA manager is in the Secure state—DMA channel operates in the Secure state.

DMA manager is in the Non-secure state—The DMAC aborts.

Operation

You can only use this instruction with the DMA manager thread.

DMAKILL

Kill instructs the DMAC to immediately terminate execution of a thread. Depending on the thread type, the DMAC performs the following steps:

DMA Manager Thread

1. Invalidates all cache entries for the DMA manager.
2. Moves the DMA manager to the Stopped state.

DMA Channel Thread

1. Moves the DMA channel to the Killing state.
2. Waits for AXI transactions, with an ID equal to the DMA channel number, to complete.
3. Invalidates all cache entries for the DMA channel.
4. Remove all entries in the MFIFO buffer for the DMA channel.
5. Remove all entries in the read buffer queue and write buffer queue for the DMA channel.
6. Moves the DMA channel to the Stopped state.

Figure 16-10: DMAKILL Instruction Encoding

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	1

Assembler syntax

DMAKILL

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

Note: You must not use the `DMAKILL` instruction in DMA channel programs. To issue a `DMAKILL` instruction, use the `DBGINST0` register.

DMALD[S | B]

Load instructs the DMAC to perform a DMA load, using AXI transactions that the source address registers and channel control registers specify. It places the read data into the MFIFO buffer and tags it with the corresponding channel number. `DMALD` is an unconditional instruction but `DMALDS` and `DMALDB` are conditional on the state of the `request_type` flag. If the `src_inc` bit in the channel control registers is set to incrementing, the DMAC updates the source address registers after it executes `DMALD[S | B]`.

Note: The DMAC sets the value of `request_type` when it executes a `DMAWFP` instruction.

Figure 16-11: `DMALD[S|B]` Instruction Encoding

Assembler syntax

`DMALD[S | B]`

where:

[S] If S is present, the assembler sets `bs` to 0 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single

The DMAC performs a `DMALD` instruction and it sets `arlen[3:0]=0x0` so that the AXI read transaction length is one. The DMAC ignores the value of the `src_burst_len` field in the channel control registers.

- `request_type` = Burst

The DMAC performs a `DMANOP` instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

[B] If B is present, the assembler sets `bs` to 1 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single

The DMAC performs a `DMANOP` instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

- `request_type` = Burst

The DMAC performs a `DMALD`.

If you do not specify the S or B operand, the assembler sets `bs` to 0 and `x` to 0, and the DMAC always executes a DMA load.

Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of `request_type` matching that of the instruction.

DMALDP<S | B>

Load and notify Peripheral instructs the DMAC to perform a DMA load, using AXI transactions that source address registers and channel control registers specify. It places the read data into a FIFO buffer that is tagged with the corresponding channel number and after it receives the last data item, it sends an acknowledgement to the peripheral that the data transfer is complete. If the `src_inc` bit in the channel control registers is set to incrementing, the DMAC updates source address registers after it executes DMALDP<S | B>.

Figure 16-12: DMALDP<S|B> Instruction Encoding

15	11	10	9	8	7	6	5	4	3	2	1	0
periph[4:0]				0	0	0	0	0	1	0	0	1
											bs	1

Assembler syntax

DMALDP<S | B> <peripheral>

where:

<S> When S is present, the assembler sets `bs` to 0. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single

The DMAC performs a DMALDP instruction and it sets `arlen[3:0]=0x0` so that the AXI read transaction length is one. The DMAC ignores the value of the `src_burst_len` field in the channel control registers.

- `request_type` = Burst

The DMAC performs a `DMANOP`.

 When B is present, the assembler sets `bs` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single

The DMAC performs a `DMANOP`.

- `request_type` = Burst

The DMAC performs a load using a burst DMA transfer.

<peripheral> 5-bit immediate, value 0-31.

Note: The DMAC sets the value of the `request_type` flag when it executes a `DMAWFP` instruction.

Operation

You can only use this instruction in a DMA channel thread. Execution of the instruction is conditional on the state of the `request_type` flag matching that of the instruction.

DMALP

Loop instructs the DMAC to load an 8-bit value into the loop counter register you specify.

This instruction indicates the start of a section of instructions, and you set the end of the section using the DMALPEND instruction. The DMAC repeats the set of instructions that you insert between DMALP and DMALPEND until the value in the loop counter register reaches zero.

Note: The DMAC saves the value of the PC for the instruction that follows DMALP. After the DMAC executes DMALPEND, and the loop counter register is not zero, this enables it to execute the first instruction in the loop.

Figure 16-13: DMALP Instruction Encoding

Assembler syntax

DMALP <loop_iterations>

where:

<loop_iterations>

Specifies the number of loops to perform, range 1-256.

- The assembler determines the loop counter register to use and either:
- Sets 1c to 0, and the DMAC writes the value loop_iterations minus 1 to the loop counter 0 registers
- Sets 1c to 1, and the DMAC writes the value loop_iterations minus 1 to the loop counter 1 registers.

Operation

You can only use this instruction in a DMA channel thread.

DMALPEND[S | B]

Loop End indicates the last instruction in the program loop but the behavior of the DMAC depends on whether DMALP or DMALPFE starts the loop. If a loop starts with:

- DMALP The loop has a defined loop count and DMALPEND[S | B] instructs the DMAC to read the value of the loop counter register. If a loop counter register returns:
 - Zero—The DMAC executes a DMANOP and therefore exits the loop.
 - Nonzero—The DMAC decrements the value in the loop counter register and updates the thread PC to contain the address of the first instruction in the program loop, that is, the instruction that follows the DMALP.
- DMALPFE The loop has an undefined loop count and the DMAC uses the state of the request_last flag to control when it exits the loop. If the request_last flag is:
 - 0—The DMAC updates the thread PC to contain the address of the first instruction in the program loop, that is, the instruction that follows the DMALP.
 - 1—The DMAC executes a DMANOP and therefore exits the loop.

Figure 16-14: DMALPEND[S|B] Instruction Encoding

**Assembler syntax**

DMALPEND[S | B]

where:

[S] If S is present and the loop starts with DMALP, then the assembler sets *bs* to 0 and *x* to 1. The instruction is conditional on the state of the *request_type* flag:

- *request_type* = Single
 - The DMAC executes the DMALPEND
- *request_type* = Burst
 - The DMAC performs a DMANOP and therefore exits the loop.

[B] If B is present and the loop starts with DMALP, then the assembler sets *bs* to 1 and *x* to 1. The instruction is conditional on the state of the *request_type* flag:

- *request_type* = Single
 - The DMAC performs a DMANOP and therefore exits the loop.
- *request_type* = Burst
 - The DMAC executes the DMALPEND

If you do not specify the S or B operand, the assembler sets *bs* to 0 and *x* to 0, and the DMAC always executes the DMALPEND.

Note: You must not specify the S or B operand when a loop starts with DMALPFE. If you do, the assembler issues a warning message and sets *bs* to 0, *x* to 0, and *nf* to 1. In the same way as for DMALPFE, the DMAC uses the state of the *request_last* flag to control when it exits the loop.

Note: The DMAC sets the value of the:

- *request_type* flag when it executes a DMAWFP instruction.
- *request_last* flag to 1 when the corresponding peripheral issues the last request command through the peripheral request interface.

To correctly assign the additional bits in the DMALPEND instruction, the assembler determines the values for:

backwards_jump[7:0] Sets the relative location of the first instruction in the program loop. The assembler calculates the value for *backwards_jump[7:0]* by subtracting the address of the first instruction in the loop from the address of the DMALPEND.

- `nf` sets it to:
 - 0 if `DMALPFE` started the program loop
 - 1 if `DMALP` started the program loop.
- `lc` sets it to:
 - 0 if the loop counter 0 registers contains the loop counter value
 - 1 if the loop counter 1 registers contains the loop counter value
 - 1 if `DMALPFE` started the program loop.

Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of the `request_type` flag matching that of the instruction.

Related Information

- [Peripheral Length Management](#) on page 16-12
- [DMAWFP](#) on page 16-42

DMALPFE

The assembler uses Loop Forever to configure certain bits in `DMALPEND`.

Note: When the assembler encounters `DMALPFE`, it does not create an instruction for the DMAC, but instead, it modifies the behavior of `DMALPEND`. The insertion of `DMALPFE` in program code identifies the start of the loop.

Assembler syntax

`DMALPFE`

Related Information

[DMALPEND\[S | B\]](#) on page 16-35

DMAMOV

Move instructs the DMAC to move a 32-bit immediate into the following registers:

- source address registers
- destination address registers
- channel control registers

Figure 16-15: DMAMOV Instruction Encoding

Assembler syntax

```
DMAMOV <destination_register>, <32-bit_immediate>
```

where:

```
<destination_register>
```

The valid registers are:

- SAR—selects the source address registers and sets *rd* to b000
- CCR—selects the channel control registers and sets *rd* to b001
- DAR—selects the destination address registers and sets *rd* to b010

```
<32-bit_immediate>
```

A 32-bit value that is written to the specified destination register.

Note: For information about using the assembler to program the various fields that the channel control registers, refer to DMAMOV CCR section

Operation

You can only use this instruction in a DMA channel thread.

Related Information

[DMAMOV CCR](#) on page 16-44

Information about using the assembler to program the various fields that the channel control registers

DMANOP

No Operation does nothing. You can use this instruction for code alignment purposes.

Figure 16-16: DMANOP Instruction Encoding

7	6	5	4	3	2	1	0
0	0	0	1	1	0	0	0

Assembler syntax

```
DMANOP
```

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

DMARMB

Read Memory Barrier forces the DMA channel to wait until all of the executed `DMALD` instructions for that channel have been issued on the AXI master interface and have completed.

This enables write-after-read sequences to the same address location with no hazards.

Figure 16-17: DMARMB Instruction Encoding

7	6	5	4	3	2	1	0
0	0	0	1	0	0	1	0

Assembler syntax

DMARMB

Operation

You can only use this instruction in a DMA channel thread.

DMASEV

Send Event instructs the DMAC to modify an event-interrupt resource. Depending on how you program the interrupt enable register, this either:

- Generates event <event_num>
 - Note:** Typically, you use `DMAWFE` to stall a thread and then another thread executes `DMASEV`, using the appropriate event number, to unSTALL the waiting thread.
- Signals an interrupt using `irq <event_num>`.

Figure 16-18: DMASEV Instruction Encoding

15	11	10	9	8	7	6	5	4	3	2	1	0
event_num[4:0]		0	0	0	0	0	1	1	0	1	0	0

Assembler syntax

DMASEV <event_num>

where:

<event_num> 5-bit immediate, value 0-31

Note: The DMAC aborts the thread if you select an event number that is not available.

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

Related Information

- [Using Events and Interrupts](#) on page 16-14
- [Using an Event to Restart DMA Channels](#) on page 16-15

DMAST[S | B]

Store instructs the DMAC to transfer data from the FIFO buffer to the location that the destination address registers specifies, using AXI transactions that the DA register and channel control registers

specify. If the `dst_inc` bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes `DMAST[S|B]`.

Figure 16-19: DMAST[S|B] Instruction Encoding

7	6	5	4	3	2	1	0
0	0	0	0	1	0	bs	x

Assembler syntax

`DMAST[S|B]`

where:

[S] If S is present, the assembler sets `bs` to 0 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single
- The DMAC performs a `DMAST` instruction and it sets `awlen[3:0]=0x0` so that the AXI write transaction length is one. The DMAC ignores the `v` value of the `dst_burst_len` field in the channel control registers.
- `request_type` = Burst
- The DMAC performs a `DMA NOP` instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

[B] If B is present, the assembler sets `bs` to 1 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single
- The DMAC performs a `DMA NOP` instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.
- `request_type` = Burst
- The DMAC performs a `DMAST`.
- If you do not specify the S or B operand, the assembler sets `bs` to 0 and `x` to 0, and the DMAC always executes a DMA store.

Note: The DMAC sets the value of the `request_type` flag when it executes a `DMAWFP` instruction.

Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of the `request_type` flag matching that of the instruction.

The DMAC only commences the burst when the MFIFO buffer contains all of the data necessary to complete the burst transfer.

Related Information

[DMAWFP](#) on page 16-42

DMASTP<S | B>

Store and notify Peripheral instructs the DMAC to transfer data from the FIFO buffer to the location that the destination address registers specifies, using AXI transactions that the DA register and channel control registers specify. It uses the DMA channel number to access the appropriate location in the FIFO

buffer. After the DMA store is complete, and the DMAC has received a buffered write response, it issues an acknowledgement to the peripheral that the data transfer is complete. If the `dst_inc` bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes `DMASTP<S|B>`.

Figure 16-20: DMASTP<S|B> Instruction Encoding

Assembler syntax

`DMASTP<S|B> <peripheral>`

where:

<S> Sets `bs` to 0. This instructs the DMAC to perform:

- A single DMA store operation if `request_type` is programmed to Single
- The DMAC ignores the state of the `dst_burst_len` field in the channel control registers and always performs an AXI transfer with a burst length of one.
- A `DMANOP` if `request_type` is programmed to Burst.

 Sets `bs` to 1. This instructs the DMAC to perform:

- The DMA store if `request_type` is programmed to Burst
- A `DMANOP` if `request_type` is programmed to Single.

<peripheral> 5-bit immediate, value 0-31.

Note: The DMAC sets the value of the `request_type` flag when it executes a `DMAWFP` instruction.

Operation

You can only use this instruction in a DMA channel thread.

The DMAC only commences the burst when the MFIFO buffer contains all of the data necessary to complete the burst transfer.

Related Information

[DMAWFP](#) on page 16-42

DMASTZ

Store Zero instructs the DMAC to store zeros, using AXI transactions that the destination address registers and channel control registers specify. If the `dst_inc` bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes `DMASTZ`.

Figure 16-21: DMASTZ Instruction Encoding

Assembler syntax

DMASTZ

Operation

You can only use this instruction in a DMA channel thread.

DMAWFE

Wait For Event instructs the DMAC to halt execution of the thread until the event, that `<event_num>` specifies, occurs. When the event occurs, the thread moves to the Executing state and the DMAC clears the event.

Figure 16-22: DMAWFE Instruction Encoding**Assembler syntax**DMAWFE `<event_num>`[, `invalid`]

where:

`<event_num>` 5-bit immediate, value 0-31

[`invalid`] Sets `i` to 1. If `invalid` is present, the DMAC invalidates the instruction cache for the current DMA thread. If `invalid` is not present, then the assembler sets `i` to 0 and the DMAC does not invalidate the instruction cache for the current DMA.

- The DMAC aborts the thread if you select an event number that is not available for your configuration of the DMAC. To ensure cache coherency, you must use `invalid` when a processor writes the instruction stream for a DMA channel.

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

Related Information

[Using Events and Interrupts](#) on page 16-14

DMAWFP

Wait For Peripheral instructs the DMAC to halt execution of the thread until the specified peripheral signals a DMA request for that DMA channel.

Figure 16-23: DMAWFP Instruction Encoding

Assembler syntax

DMAWFP <peripheral>, <single|burst|periph>

where:

<peripheral> 5-bit immediate, value 0-31

Note: The DMAC aborts the thread if you select a peripheral number that is not available.

<single> Sets *bs* to 0 and *p* to 0. This instructs the DMAC to continue executing the DMA channel thread after it receives a single or burst DMA request. The DMAC sets the *request_type* to Single, for that DMA channel.

<burst> Sets *bs* to 1 and *p* to 0. This instructs the DMAC to continue executing the DMA channel thread after it receives a burst DMA request. The DMAC sets the *request_type* to Burst.

Note: The DMAC ignores single burst DMA requests.

<periph> Sets *bs* to 0 and *p* to 1. This instructs the DMAC to continue executing the DMA channel thread after it receives a single or burst DMA request. The DMAC sets the *request_type* to:

- **Single:** When it receives a single DMA request.
- **Burst:** When it receives a burst DMA request.

Operation

You can only use this instruction in a DMA channel thread.

DMAWMB

Write Memory Barrier forces the DMA channel to wait until all of the executed *DMAST* instructions for that channel have been issued on the AXI master interface and have completed.

This permits read-after-write sequences to the same address location with no hazards.

Figure 16-24: DMAWMB Instruction Encoding

Assembler syntax

DMAWMB

Operation

You can only use this instruction in a DMA channel thread.

Assembler Directives

The assembler provides several additional commands.

DCD

Assembler directive to place a 32-bit immediate in the instruction stream.

Syntax

DCD imm32

DCB

Assembler directive to place an 8-bit immediate in the instruction stream.

Syntax

DCB imm8

DMALP

Assembler directive to insert an iterative loop.

Syntax

DMALP [<LC0>|<LC1>] <loop_iterations>

where:

<loop_iterations>

An 8-bit value that specifies the number of loops to perform.

Note: For clarity in writing assembler instructions, the 8-bit value is the actual number of iterations of the loop to be executed. The assembler decrements this by one to create the actual value, 0-255, that the DMAC uses.

[LC0] If LC0 is present, the DMAC stores <loop_iterations> in the loop counter 0 registers.

[LC1] If LC1 is present, the DMAC stores <loop_iterations> in the loop counter 1 registers.

Note: If LC0 or LC1 is not present, the assembler determines the loop counter register to use.

DMALPFE

Assembler directive to insert a repetitive loop.

Syntax

DMALPFE

Enables the assembler to clear the nf bit that is present in DMALPEND[S | B].

DMAMOV CCR

Assembler directive that enables you to program the channel control registers using the specified format.

Syntax

DMAMOV CCR,

[SB<1-16>] [SS<8|16|32|64|128>] [SA<I|F>]

[SP<imm3>] [SC<imm4>]

[DB<1-16>] [DS<8|16|32|64|128>] [DA<I|F>]

[DP<imm3>] [DC<imm4>]

[ES<8|16|32|64|128>]

Table 16-4: DMAMOV CCR Argument Description and Default Values

Syntax	Description	Options	Default
SA	Source address increment. Sets the value of <code>arburst[0]</code>	I = Increment F = Fixed	I
SS	Source burst size in bits. Sets the value of <code>arsize[2:0]</code>	8, 16, 32, or 64	8
SB	Source burst length. Sets the value of <code>arlen[3:0]</code>	1 to 16	1
SP	Source protection	0 to 7 ⁽⁴⁵⁾	0
SC	Source cache	0 to 15 ⁽⁴⁵⁾⁽⁴⁶⁾	0
DA	Destination address increment. Sets the value of <code>awburst[0]</code>	I = Increment F = Fixed	I
DS	Destination burst size in bits. Sets the value of <code>awsize[2:0]</code>	8, 16, 32, or 64	8
DB	Destination burst length. Sets the value of <code>awlen[3:0]</code>	1 to 16	1
DP	Destination protection	0 to 7 ⁽⁴⁵⁾	0
DC	Destination cache	0 to 15 ⁽⁴⁵⁾⁽⁴⁷⁾	0
ES	Endian swap size, in bits	8, 16, 32, or 64	8

MFIFO Buffer Usage Overview

About MFIFO Buffer Usage Overview

The MFIFO buffer is a shared resource that is utilized on a first-come, first-served basis by all currently active channels. To a program, it appears as a set of variable-depth parallel FIFO buffers, one per channel, with the restriction that the total depth of all the FIFOs cannot exceed the size of the MFIFO, which is 512 entries. The width of the AXI master interface is the same as the MFIFO buffer width.

The DMAC is capable of realigning data from the source to the destination. For example, the DMAC shifts the data by two byte lanes when it reads a word from address 0x103 and writes to address 0x205. All byte manipulations occur when data enters the MFIFO buffer, as a result of an AXI read due to a `DMALD`

⁽⁴⁵⁾ You must use decimal values when programming this immediate value.

⁽⁴⁶⁾ Because the DMAC ties `ARCACHE[3]` low, the assembler always sets bit 3 to 0 and uses bits [2:0] of your chosen value for SC.

⁽⁴⁷⁾ Because the DMAC ties `AWCACHE[2]` low, the assembler always sets bit 2 to 0 and uses bit [3] and bits [1:0] of your chosen value for DC.

instruction, so that the DMAC does not need to manipulate the data when it removes it from the MFIFO buffer, as a result of an AXI write due to a `DMAST` instruction. Therefore the storage and packing of the data in the MFIFO buffer is determined by the destination address and transfer characteristics.

When a program specifies that incrementing transactions are to be performed to the destination, the DMAC packs data into the MFIFO buffer to minimize the usage of the MFIFO buffer entries. For example, the DMAC packs two 32-bit words into a single entry in the MFIFO buffer when the program uses a source address of `0x100`, and destination address of `0x200`.

The number of entries required to store the data loaded from a source is not a simple calculation of amount of source data divided by MFIFO buffer width in the following situations:

- The source address is not aligned to the AXI bus width.
- The destination address is not aligned to the AXI bus width.
- The transactions are to a fixed destination, that is, a non-incrementing address.

The `DMALD` and `DMAST` instructions each specify that an AXI transaction is to be performed. The amount of data transferred by an AXI transaction depends on the values programmed in to the `CCR n` register and the address of the transaction.

The following sections provide several example DMAC programs together with illustrations of the MFIFO buffer usage.

Note: These sections show MFIFO buffer usage in the following ways:

- A graph of the number of MFIFO buffer entries versus time
- A diagram of the byte-lane manipulation that the DMAC performs when data enters the MFIFO buffer.

Note: The numbers 0 and 7 in the MFIFO buffer diagrams indicate the byte lanes in the MFIFO buffer.

Information about unaligned transfers available from the ARM info center website.

Aligned Transfers

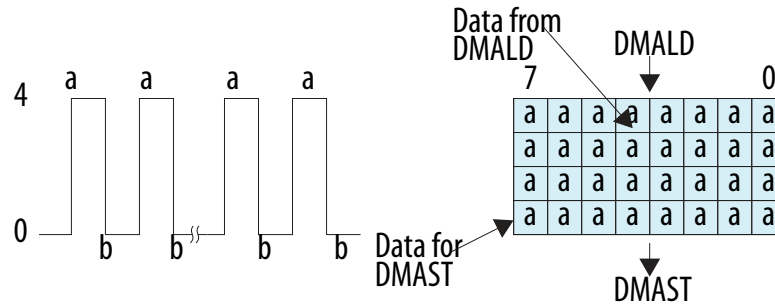

Simple Aligned Program

The following program shows the MFIFO buffer usage. In this program, the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD    ; shown as a in figure below
            DMAST    ; shown as b in figure below
DMALPEND
DMAEND
```

Figure 16-25: Simple Aligned Program

Each DMALD requires four entries and each DMAST removes four entries.

This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

Aligned Asymmetric Program with Multiple Loads

The following program performs four loads for each store and the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB1 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD    ; shown as a in the figure below
    DMALD   ; shown as b in the figure below
    DMALD   ; shown as c in the figure below
    DMALD   ; shown as d in the figure below
    DMAST   ; shown as e in the figure below
DMALPEND
DMAEND
```

Figure 16-26: Aligned Asymmetric Program with Multiple Loads

Each DMALD requires one entry and each DMAST removes four entries.

This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

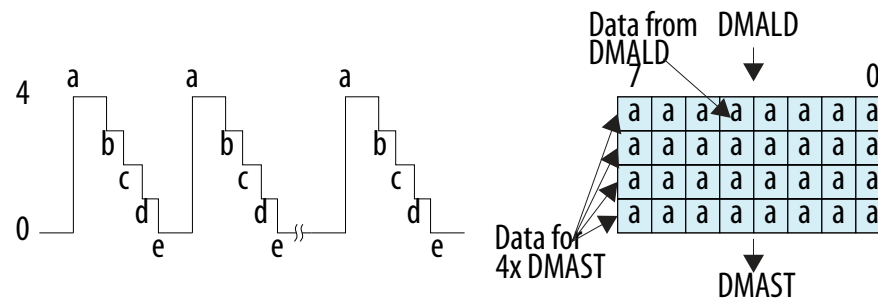

Aligned Asymmetric Program with Multiple Stores

The following program performs four stores for each load and the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB4 SS64 DB1 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD ; shown as a in the figure below
    DMAST ; shown as b in the figure below
    DMAST ; shown as c in the figure below
    DMAST ; shown as d in the figure below
    DMAST ; shown as e in the figure below
DMALPEND
DMAEND
```

Figure 16-27: Aligned Asymmetric Program with Multiple Stores

Each DMALD requires four entries and each DMAST removes one entry.

This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

Unaligned Transfers

Aligned Source Address to Unaligned Destination Address

In the following program, the source address is aligned with the AXI data bus width but the destination address is unaligned. The destination address is not aligned to the destination burst size so the first DMAST instruction removes less data than the first DMALD instruction reads. Therefore, a final DMAST of a single word is required to clear the data from the MFIFO buffer.

```
DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4004
DMALP 16
    DMALD ; shown as a1, ... a, an in the figure below
    DMAST ; shown as b in the figure below
DMALPEND
DMAMOV CCR, SB4 SS64 DB1 DS32
DMAST ; shown as c in the figure below
DMAEND
```

Figure 16-28: Aligned to Unaligned Program

The first `DMALD` instruction loads four doublewords but because the destination address is unaligned, the `DMAC` shifts them by four bytes and therefore uses five entries in the MFIFO buffer.

Each `DMAST` requires only four entries of data, and therefore the extra entry remains in use for the duration of the program, until it is emptied by the last `DMAST`.

This example has a static requirement of one MFIFO buffer entry and a dynamic requirement of four MFIFO buffer entries.

Unaligned Source Address to Aligned Destination Address

In this program, the source address is unaligned with the AXI data bus width but the destination address is aligned. The source address is not aligned to the source burst size so the first `DMALD` instruction reads in less data than the `DMAST`. Therefore, an extra `DMALD` is required to satisfy the first `DMAST`.

```

DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1004
DMAMOV DAR, 0x4000
DMALD ; shown as a in the figure below
DMALP 15
    DMALD ; shown as b1, ... b, bn in the figure below
    DMAST ; shown as c in the figure below
DMALPEND
DMAMOV CCR, SB1 SS32 DB4 DS64
DMALD ; shown as d in the figure below
DMAST ; shown as e in the figure below
DMAEND
    
```

Figure 16-29: Unaligned to Aligned Program

The first `DMALD` instruction does not load sufficient data to enable the DMAC to execute a `DMAST` and therefore the program includes an additional `DMALD`, prior to the start of the loop.

After the first `DMALD`, the subsequent `DMALDs` align with the source burst size. This optimizes the `b` performance but it requires a larger number of MFIFO buffer entries.

Note: The `DMALD` shown as `a` does not increase the MFIFO buffer usage because it loads four bytes into an MFIFO buffer entry that the DMAC has already allocated to this channel.

This example has a static requirement of four MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

Unaligned Source Address to Aligned Destination Address with Excess Initial Load

This program is an alternative to that described in *Unaligned Source Address to Aligned Destination Address*. The program executes a different sequence of source bursts that might be less efficient, but requires fewer MFIFO buffer entries.

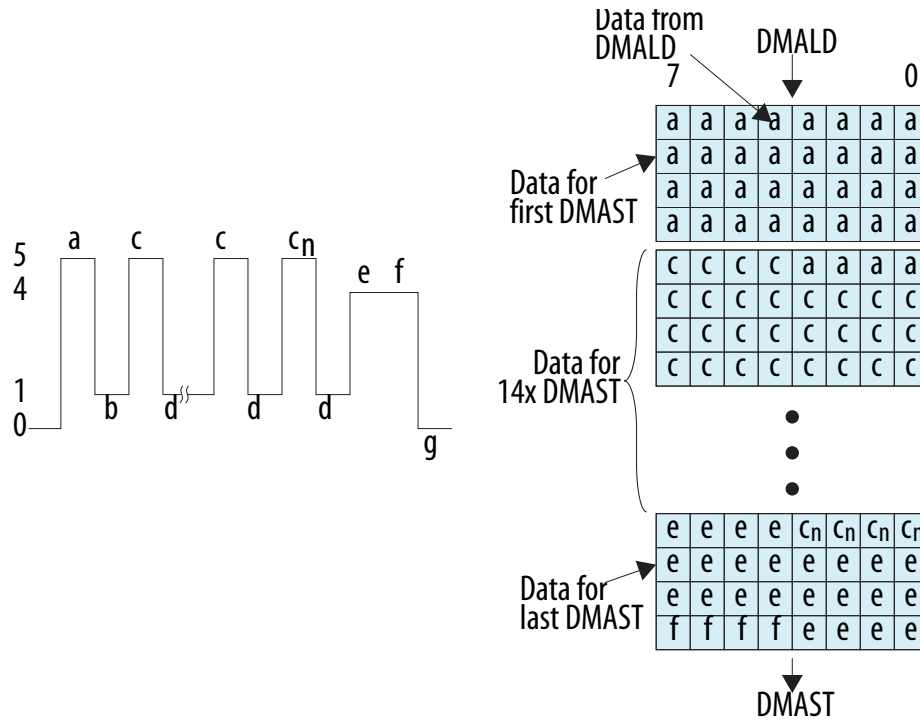

```
DMAMOV CCR, SB5 SS64 DB4 DS64
DMAMOV SAR, 0x1004
DMAMOV DAR, 0x4000
DMALD ; shown as a in the figure below
DMAST ; shown as b in the figure below
DMAMOV CCR, SB4 SS64 DB4 DS64
DMALP 14
    DMALD ; shown as c and cn in the figure below
        DMAST ; shown as d in the figure below
DMALPEND
DMAMOV CCR, SB3 SS64 DB4 DS64
DMALD ; shown as e in the figure below
```

```
DMAMOV CCR, SB1 SS32 DB4 DS64
DMALD ; shown as f in the figure below
DMAST ; shown as g in the figure below
DMAEND
```

Figure 16-30: Unaligned to Aligned with Excess Initial Load

The first DMALD instruction loads five bursts of data to enable the DMAC to execute the first DMAST.

After the first DMALD, the subsequent DMALDs are not aligned to the source burst size, for example the second DMALD reads from address 0x1028. After the loop, the final two DMALDs read the data required to satisfy the final DMAST.

Note: The DMALD shown as **f** does not increase the MFIFO buffer usage because it loads four bytes into an MFIFO buffer entry that the DMAC has already allocated to this channel.

This example has a static requirement of one MFIFO buffer entry and a dynamic requirement of four MFIFO buffer entries.

Related Information

[Unaligned Source Address to Aligned Destination Address](#) on page 16-49

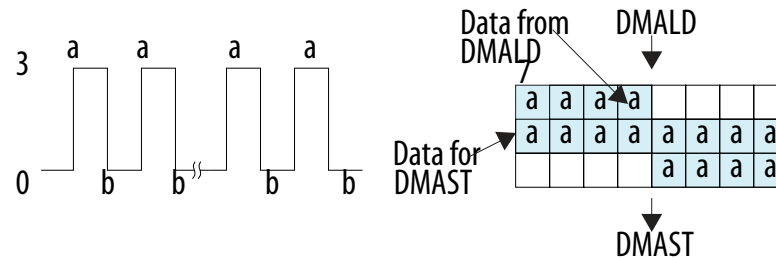

Aligned Burst Size Unaligned MFIFO Buffer

In this program, the destination address, which is narrower than the MFIFO buffer width, aligns with the burst size, but does not align with the MFIFO buffer width.

```
DMAMOV CCR, SB4 SS32 DB4 DS32
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4004
DMALP 16
```

DMALD ; shown as a in the figure below
 DMAST ; shown as b in the figure below
 DMALPEND
 DMAEND

Figure 16-31: Aligned Burst with Unaligned MFIFO Buffer Width

In this example, the destination address is not 64-bit aligned, it requires three rather than the expected two MFIFO buffer entries.

This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of three MFIFO buffer entries.

Fixed Transfers

Fixed Destination with Aligned Address

In this program, the source address and destination address are aligned with the AXI data bus width, and the destination address is fixed.

```
DMAMOV CCR, SB2 SS64 DB4 DS32 DAF
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD ; shown as a in the figure below
    DMAST ; shown as b in the figure below
DMALPEND
DMAEND
```

Figure 16-32: Fixed Destination with Aligned Address

Each DMALD in the program loads two 64-bit data transfers into the MFIFO buffer. Because the destination address is a 32-bit fixed address, then the DMAC splits each 64-bit data item across two entries in the MFIFO buffer.

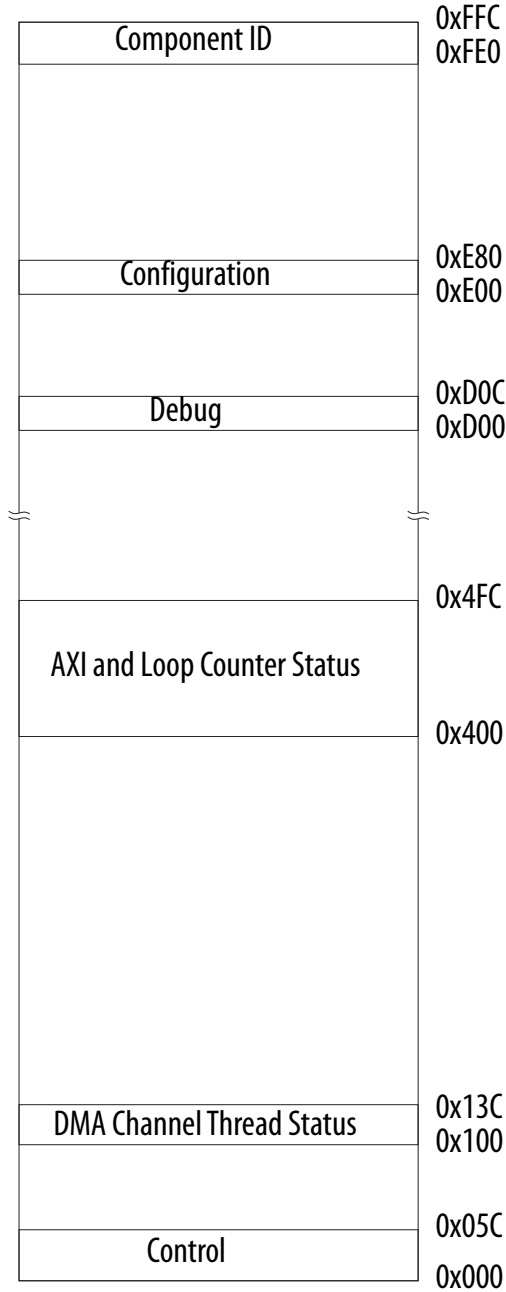

This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

DMA Controller Registers

The following DMAC register map spans a 4 KB region, consists of the following sections.

Figure 16-33: DMAC Summary Register Map

- **Control registers**— allow you to control the DMAC.
- **DMA channel thread status registers**—provide the status of the DMA channel threads.
- **AXI and loop counter status registers**—provide the AXI transfer status and the loop counter status for each DMA channel thread.
- **Debug registers**—enable the following functionality:
 - Allow you to send instructions to a thread when debugging the program code.
 - Allow system firmware to send instructions to the DMA manager thread.
- **Configuration registers**—enable system firmware to identify the configuration of the DMAC and control the behavior of the watchdog.
- **Component ID registers**— enable system firmware to identify peripherals. Do not attempt to access reserved or unused address locations. Attempting to access these locations can result in an unpredictable behavior.

Send Feedback

The hard processor system (HPS) provides two Ethernet media access controller (EMAC) peripherals. Each EMAC can be used to transmit and receive data at 10/100/1000 Mbps over Ethernet connections in compliance with the IEEE 802.3 specification. The EMACs are instances of the Synopsys DesignWare 3504-0 Universal 10/100/1000 Ethernet MAC (DWC_gmac).

The EMAC has an extensive memory-mapped control and status register (CSR) set, which can be accessed by the ARM Cortex-A9[®] MPCore.

For an understanding of this chapter, you should be familiar with the basics of IEEE 802.3 media access control (MAC).⁽⁴⁸⁾

Features of the Ethernet MAC

MAC

- IEEE 802.3-2008 compliant
- Data rates of 10/100/1000 Mbps
- Full duplex and half duplex modes
 - IEEE 802.3x flow control automatic transmission of zero-quantum pause frame on flow control input deassertion
 - Optional forwarding of received pause control frames to the user
 - Packet bursting and frame extension in 1000 Mbps half-duplex
 - IEEE 802.3x flow control in full-duplex
 - Back-pressure support for half-duplex
- 4 KB TX FIFO RAM and 4 KB RX FIFO RAM with ECC support
- IEEE 1588-2002 and IEEE 1588-2008 precision networked clock synchronization
- IEEE 802.3-az, version D2.0 for Energy Efficient Ethernet (EEE)
- IEEE 802.1Q virtual local area network (VLAN) tag detection for reception frames
- Preamble and start-of-frame data (SFD) insertion in transmit and deletion in receive paths
- Automatic cyclic redundancy check (CRC) and pad generation controllable on a per-frame basis
- Options for automatic pad/CRC stripping on receive frames
- Programmable frame length supporting standard and jumbo Ethernet frames (with size up to 9.6 KB)
- Programmable inter-frame gap (IFG), from 40- to 96-bit times in steps of eight
- Preamble of up to 1 byte supported
- Supports internal loopback asynchronous FIFO on the GMII/MII for debugging
- Supports a variety of flexible address filtering modes
 - Up to 31 additional 48-bit perfect destination address (DA) filters with masks for each byte
 - Up to 31 48-bit source address (SA) comparison check with masks for each byte
 - 256-bit hash filter (optional) for multicast and unicast DAs
 - Option to pass all multicast addressed frames
 - Promiscuous mode support to pass all frames without any filtering for network monitoring
 - Passes all incoming packets (as per filter) with a status report

DMA

- 32-bit interface
- Programmable burst size for optimal bus utilization
- Single-channel mode transmit and receive engines
- Byte-aligned addressing mode for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptors can each transfer up to 8 KB of data
- Independent DMA arbitration for transmit and receive with fixed priority or round robin

Management Interface

- 32-bit host interface to CSR set
- Comprehensive status reporting for normal operation and transfers with errors
- Configurable interrupt options for different operational conditions
- Per-frame transmit/receive complete interrupt control
- Separate status returned for transmission and reception packets

Acceleration

Transmit and receive checksum offload for transmission control protocol (TCP), user datagram protocol (UDP), or Internet control message protocol (ICMP) over Internet protocol (IP)

PHY Interface

Different external PHY interfaces are provided depending on whether the Ethernet Controller signals are routed through the HPS I/O pins or the FPGA I/O pins.

The PHY interfaces supported using the HPS I/O pins are:

- Reduced Gigabit Media Independent Interface (RGMII)

The PHY interfaces supported using adaptor logic to route signals to the FPGA I/O pins are:

- Media Independent Interface (MII)
- Gigabit Media Independent Interface (GMII)
- Reduced Media Independent Interface (RMII)
- Reduced Gigabit Media Independent Interface (RGMII)
- Serial Gigabit Media Independent Interface (SGMII) supported through the GMII to FPGA fabric with additional external conversion logic

The Ethernet Controller has two choices for the management control interface used for configuration and status monitoring of the PHY:

- Management Data Input/Output (MDIO)
- I²C PHY management through a separate I²C module within the HPS

EMAC Block Diagram and System Integration

Figure 17-1: EMAC System Integration

The EMACs are integrated into the HPS portion of the system on a chip (SoC) device. They communicate with the I/O pins.

EMAC Signal Descriptions

The EMAC provides a variety of PHY interfaces and control options through the HPS and the FPGA I/Os.

For designs in which the HPS is pin-limited, the EMAC signals can be routed through the FPGA as any one of the following interfaces by using soft adaptor logic in the FPGA:

- RMII/RGMII
- MII/GMII
- SGMII with some additional external logic

The figure below depicts a design which routes the EMAC0 and EMAC1 signals through the FPGA to provide an RMII and SGMII interface.

Refer to the *Ethernet MAC Programming Model* section to find out more information about configuring EMAC interfaces through FPGA.

Figure 17-2: EMAC to FPGA Routing Example

Note: The Micrel KSZ9021RN Ethernet PHY has been verified to work properly with the HPS EMAC and is recommended for use in board design.

HPS EMAC I/O Signals

The following table lists the EMAC signals that are routed to the HPS pins. These signals provide the RGMII interface.

Table 17-1: HPS EMAC I/O Signals

EMAC Port		In/Out	Width	Description
clk_tx_i	Transmit Clock	Out	1	This signal provides the transmit clock for RGMII (125/25/2.5 MHz in 1G/100M/10Mbps) and RMII (50 MHz in 100M / 10 Mbps). All PHY transmit signals generated by the EMAC are synchronous to this clock.
phy_txd_o	PHY Transmit Data	Out	8	This group of eight transmit data signals is driven by the MAC. Bits [3:0] provide the RGMII transmit data, and bits [1:0] provide the RMII transmit data. Unused bits in the RGMII and RMII interface configuration are tied low. In RGMII mode, the data bus carries transmit data at double rate and are sampled on both the rising and falling edges of the transmit clock. The validity of the data is qualified with phy_txen_o.
phy_txen_o	PHY Transmit Data Enable	Out	1	This signal is driven by the EMAC component, and in RGMII mode acts as the control signal (rgmii_tctl) for the transmit data, and is driven on both edges of the transmit clock, phy_txclk_o.
phy_clk_rx_i	Receive Clock	In	1	In RGMII mode, this clock frequency is 125/25/2.5 MHz in 1 G/100 M/10 Mbps modes. It is provided by the external PHY. All PHY signals received by the EMAC are synchronous to this clock.
phy_rxd_i	PHY Receive Data	In	8	These eight data signals are received from the PHY and carry receive data at double rate with bits[3:0] valid on the rising edge of phy_rxclk_i, and bits[7:4] valid on the falling edge of phy_rxclk_i. The validity of the data is qualified with phy_rxdv_i.

EMAC Port		In/Out	Width	Description
phy_rxdv_i	PHY Receive Data Valid	In	1	This signal is driven by PHY and functions are the receive control signal used to qualify the data received on phy_rxd_i. This signal is sampled on both edges of the clock.

FPGA EMAC I/O Signals

Table 17-2: FPGA EMAC I/O Signals

Signal Name	In/Out	Width	Description
phy_clk_tx_i	In	1	This is the transmit clock (2.5 MHz/25 MHz) provided by the MII PHYs only. This clock comes from the FPGA Interface and is used for TX data capture. This clock is not used in GMII mode. Note: This clock must be able to perform glitch free switching between 2.5 and 25 MHz.
phy_txclk_o	Out	1	In GMII mode, this signal is the transmit clock output to the PHY to sample data. For MII, this clock is unused.
phy_txd_o	Out	8	These are a group of eight transmit data signals driven by the EMAC. All eight bits provide the GMII transmit data byte. For the lower speed MII operation, only the bits[3:0] are used. The validity of the data is qualified with phy_txen_o and phy_txer_o. Synchronous to phy_txclk_o.
phy_txen_o	Out	1	This signal is driven by the EMAC and is used in GMII mode. When driven high, this signal indicates that valid data is being transmitted on the clk_tx_o bus.

Signal Name		In/Out	Width	Description
phy_txer_o	PHY Transmit Error	Out	1	This signal is driven by the EMAC and when high, indicates a transmit error or carrier extension on the phy_txd bus. It is also used to signal low power states in Energy Efficient Ethernet operation.
rst_clk_tx_n_o	Transmit Clock Reset output	Out	1	Transmit clock reset output to the FPGA fabric, which is the internal synchronized reset to clk_tx_int output from the EMAC. May be used by logic implemented in the FPGA fabric as desired.
phy_clk_rx_i	Receive Clock	In	1	Receive clock from external PHY. For GMII, the clock frequency is 125 MHz. For MII, the receive clock is 25 MHz for 100 Mbps and 2.5 MHz for 10 Mbps.
phy_rxd_i	PHY Receive Data	In	8	This is an eight-bit receive data bus from the PHY. In GMII mode, all eight bits are driven. The validity of the data is qualified with phy_rxdv_i and phy_rxer_i. For lower speed MII operation, only bits [3:0] are driven. These signals are synchronous to phy_clk_rx_i.
phy_rxdv_i	PHY Receive Data Valid	In	1	This signal is driven by PHY. In GMII mode, when driven high, it indicates that the data on the phy_rxd bus is valid. It remains asserted continuously from the first recovered byte of the frame through the final recovered byte.
phy_rxer_i	PHY Receive Error	In	1	This signal indicates an error or carrier extension (GMII) in the received frame. This signal is synchronous to phy_clk_rx_i and is not used in RGMII mode.
rst_clk_rx_n_o	Receive clock reset output.	Out	1	Receive clock reset output.

Signal Name		In/Out	Width	Description
phy_crs_i	PHY Carrier Sense	In	1	This signal is asserted by the PHY when either the transmit or receive medium is not idle. The PHY de-asserts this signal when both transmit and receive interfaces are idle. This signal is not synchronous to any clock.
phy_col_i	PHY Collision Detect	In	1	This signal, valid only when operating in half duplex, is asserted by the PHY when a collision is detected on the medium. This signal is not synchronous to any clock.

Related Information

[EMAC FPGA Interface Initialization](#) on page 17-59
Information on how to initialize GMII/MII interface

PHY Management Interface

The HPS can provide support for either MDIO or I²C PHY management interfaces.

MDIO Interface

The MDIO interface signals are synchronous to 14_mp_clk in all supported modes.

Note: Both the HPS and FPGA support MDIO interface I/O.

Table 17-3: PHY MDIO Management Interface

Signal	In/Out	Width	Description
gmii_mdi_i	In	1	Management Data In. The PHY generates this signal to transfer register data during a read operation. This signal is driven synchronously with the gmii_mdc_o clock.
gmii_mdo_o	Out	1	Management Data Out. The EMAC uses this signal to transfer control and data information to the PHY.
gmii_mdo_o_e	Out	1	Management Data Output Enable. This enable signal drives the gmii_mdo_o signal from an external three-state I/O buffer. This signal is asserted whenever valid data is driven on the gmii_mdo_o signal. The active state of this signal is high.

Signal	In/Out	Width	Description
gmii_md_c_o	Out	1	Management Data Clock. The EMAC provides timing reference for the gmii_md_i and gmii_md_o_o signals on MII through this aperiodic clock. The maximum frequency of this clock is 2.5 MHz. This clock is generated from the application clock through a clock divider.

I²C External PHY Management Interface

Some PHY devices use the I²C instead of MDIO for their control interface. Small form factor pluggable (SFP) optical or pluggable modules are often among those with this interface.

The HPS or FPGA can use two of the four general purpose I²C peripherals for controlling the PHY devices:

- I2C2 at base address 0xFFC06000
- I2C3 at base address 0xFFC07000

EMAC Internal Interfaces

DMA Master Interface

The DMA interface acts as a bus master on the system interconnect. Two types of data are transferred on the interface: data descriptors and actual data packets. The interface is very efficient in transferring full duplex Ethernet packet traffic. Read and write data transfers from different DMA channels can be performed simultaneously on this port, except for transmit descriptor reads and write-backs, which cannot happen simultaneously.

DMA transfers are split into a software configurable number of burst transactions on the interface. The `AXI_Bus_Mode` register in the `dmagrp` group is used to configure bursting behavior.

The interface assigns a unique ID for each DMA channel and also for each read DMA or write DMA request in a channel. Data transfers with distinct IDs can be reordered and interleaved.

The DMA interface can be configured to perform cacheable accesses. This configuration can be done in the System Manager when the DMA interface is inactive.

Write data transfers are generally performed as posted writes with OK responses returned as soon as the system interconnect has accepted the last beat of a data burst. Descriptors (status or timestamp), however, are always transferred as non-posted writes in order to prevent race conditions with the transfer complete interrupt logic.

The slave may issue an error response. When that happens, the EMAC disables the DMA channel that generated the original request and asserts an interrupt signal. The host must reset the EMAC with a hard or soft reset to restart the DMA to recover from this condition.

The EMAC supports up to 16 outstanding transactions on the interface. Buffering outstanding transactions smooths out back pressure behavior improving throughput when resource contention bottlenecks arise under high system load conditions.

Timestamp Interface

The timestamp clock reference can come from either the Clock Manager or the FPGA fabric. If the FPGA has implemented the serial capturing of the timestamp interface, then the FPGA must provide the PTP clock reference.

In addition to providing a timestamp clock reference, the FPGA can monitor the pulse-per-second output from each EMAC module and trigger a snapshot from each auxiliary time stamp timer.

The following table lists the EMAC to FPGA IEEE1588 Timestamp Interface signals to and from each EMAC module.

Table 17-4: EMAC to FPGA IEEE 1588 Timestamp Interface Signals

Signal Name	In/Out	Width	Description
f2h_emac_ptp_ref_clk	In	1	Timestamp PTP Clock reference from the FPGA Used as PTP Clock reference for each EMAC when the FPGA has implemented Timestamp capture interface. Common for all 3 EMACs.
ptp_pps_o	Out	1	Pulse Per Second Output This signal is asserted based on the PPS mode selected in the Register 459 (PPS Control Register). Otherwise, this pulse signal is asserted every time the seconds counter is incremented. This signal is synchronous to f2h_emac_ptp_ref_clk and may only be sampled if the FPGA clock is used as timestamp reference.
ptp_aux_ts_trigger_i	In	1	Auxiliary Timestamp Trigger This signal is asserted to take an auxiliary snapshot of the time. The rising edge of this internal signal is used to trigger the auxiliary snapshot. The signal is synchronized internally with clk_ptp_ref_i which results in an additional delay of 3 cycles. This input is asynchronous input and its assertion period must be greater than 2 PTP active clocks to be sampled.

Functional Description of the EMAC

Figure 17-3: EMAC High-Level Block Diagram with Interfaces

There are two host interfaces to the Ethernet MAC. The management host interface, a 32-bit slave interface, provides access to the CSR set regardless of whether or not the EMACs are used directly through the FPGA fabric. The data interface is a 32-bit master interface, and it controls data transfer between the direct memory access (DMA) controller channels and the rest of the HPS system through the system interconnect.

The built-in DMA controller is optimized for data transfer between the MAC controller and system memory. The DMA controller has independent transmit and receive engines and a CSR set. The transmit engine transfers data from system memory to the device port, while the receive engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal host intervention.

The EMAC also contains FIFO buffer memory to buffer and regulate the Ethernet frames between the application system memory and the EMAC module. Each EMAC module has one 4 KB TX FIFO and one 4 KB RX FIFO. On transmit, the Ethernet frames write into the transmit FIFO buffer, and eventually trigger the EMAC to perform the transfer. Received Ethernet frames are stored in the receive FIFO buffer and the FIFO buffer fill level is communicated to the DMA controller. The DMA controller then initiates the configured burst transfers. Receive and transmit transfer statuses are read by the EMAC and transferred to the DMA.

Transmit and Receive Data FIFO Buffers

Each EMAC component has associated transmit and receive data FIFO buffers to regulate the frames between the application system memory and the EMAC. Both FIFO buffer instances are 1024 x 42 bits. The FIFO buffer word consists of:

- Data: 32 bits
- Sideband:
 - Byte enables (BE): 2 bits
 - End of frame (EOF): 1 bit
 - Error correction code (ECC): 7 bits

The data and sideband are protected by the 7-bit single error correct, double error detect (SECDED) code word.

The FIFO buffer RAMs have ECC enable, error injection and status pins. The enable and error injection pins are inputs driven by the system manager. The status pins are outputs driven to the MPU subsystem.

Note: The ECC block provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single-bit and double-bit errors for test purposes.

TX FIFO

The time at which data is sent from the TX FIFO to the EMAC is dependent on the transfer mode selected:

- Threshold mode: Data is popped from the TX FIFO when the number of bytes in the TX FIFO crosses the configured threshold level (or when the end of the frame is written before the threshold is crossed). The threshold level is configured using the `TTC` bit of Register 0 (Bus Mode Register).
- Store-and-Forward mode: Data is popped from the TX FIFO when one or more of the following conditions are true:
 - A complete frame is stored in the FIFO
 - The TX FIFO becomes almost full
 - The ATI watermark level becomes low. This case is only applicable when the Application Interface is used. The watermark becomes low when the requested FIFO does not have space to accommodate the requested burst length on the ATI.

The application can flush the TX FIFO of all contents by setting bit 20 (`FTF`) of Register 6 (Operation Mode Register). This bit is self-clearing and initializes the FIFO pointers to the default state. If the `FTF` bit is set during a frame transfer to the EMAC, further transfers are stopped because the FIFO is considered empty. This cessation causes an underflow event and a runt frame to be transmitted and the corresponding status word is forwarded to the DMA.

If a collision occurs in half-duplex mode operation before an end of the frame, the EMAC retries by popping the TX FIFO contents again.

Note: After more than 96 bytes (or 548 bytes in 1000 Mbps mode) are popped to the EMAC, the TX FIFO controller frees that space and makes it available to the DMA and a retry is not possible.

Note: When transmitting jumbo frames, the checksum offload feature must be disabled. Only packets of 4 KB or less can be supported when the checksum offload feature is enabled by software.

RX FIFO

Frames received by the EMAC are pushed into the RX FIFO. The fill level of the RX FIFO is indicated to the DMA when it crosses the configured receive threshold which is programmed by the `RTC` field of Register 6 (Operation Mode Register). The time at which data is sent from the RX FIFO to the DMA is dependent on the configuration of the RX FIFO:

- Cut-through (default) mode: When 64 bytes or a full packet of data is received into the FIFO, data is popped out of the FIFO and sent to the DMA until a complete packet has been transferred. Upon completion of the end-of-frame transfer, the status word is popped and sent to the DMA.
- Store and forward mode: A frame is read out only after being written completely in the RX FIFO. This mode is configured by setting the `RSF` bit of Register 6 (Operation Mode Register).

If the RX FIFO is full before it receives the EOF data from the EMAC, an overflow is declared and the whole frame (including the status word) is dropped and the overflow counter in the DMA, (Register 8) Missed Frame and Buffer Overflow Counter Register, is incremented. This outcome is true even if the Forward Error Frame (`FEF`) bit of Register 6 (Operation Mode Register) is set. If the start address of such a frame has already been transferred, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with the status word. The status indicates a partial frame because of overflow. In such frames, the Frame Length field is invalid. If the RX FIFO is configured to operate in the store-and-forward mode and if the length of the received frame is more than the FIFO size, overflow occurs and all such frames are dropped.

Note: In store-and-forward mode, only received frames with length 4 KB or less prevent overflow errors and frames from being dropped.

DMA Controller

The DMA has independent transmit and receive engines, and a CSR space. The transmit engine transfers data from system memory to the device port or MAC transaction layer (MTL), while the receive engine transfers data from the device port to the system memory. Descriptors are used to efficiently move data from source to destination with minimal Host CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the Host CPU for situations such as frame transmit and receive transfer completion as well as error conditions.

The DMA and the Host driver communicate through two data structures:[†]

- Control and Status registers (CSR)[†]
- Descriptor lists and data buffers[†]

Descriptor Lists and Data Buffers[†]

The DMA transfers data frames received by the MAC to the receive Buffer in the Host memory, and transmit data frames from the transmit Buffer in the Host memory. Descriptors that reside in the Host memory act as pointers to these buffers.[†]

There are two descriptor lists: one for reception and one for transmission. The base address of each list is written into Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register), respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both receive and transmit descriptors (`RDES1[24]` and `TDES1[24]`). The descriptor lists reside in the Host physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.[†]

A data buffer resides in the Host physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when end-of-frame is detected. Data chaining can be enabled or disabled.†

Figure 17-4: Descriptor Ring Structure

Figure 17-5: Descriptor Chain Structure

Note: You can select a descriptor structure during RTL configuration. The control bits in the descriptor structure are assigned so that the application can use an 8 KB buffer. All descriptions refer to the default descriptor structure.

Host Bus Burst Access

The DMA attempts to execute fixed-length burst transfers on the master interface if configured to do so through the `FB` bit of Register 0 (`Bus Mode Register`). The maximum burst length is indicated and limited by the `PBL` field (Bits [13:8]) Register 0 (`Bus Mode Register`). The receive and transmit descriptors are always accessed in the maximum possible (limited by packet burst length (`PBL`) or $16 * 8$ /bus width) burst size for the 16- bytes to be read.

The transmit DMA initiates a data transfer only when the MTL transmit FIFO has sufficient space to accommodate the configured burst or the number of bytes remaining in the frame (when it is less than the configured burst length). The DMA indicates the start address and the number of transfers required to the master interface. When the interface is configured for fixed-length burst, it transfers data using the best combination of `INCR4`, 8, or 16 and `SINGLE` transactions. When not configured for fixed-length burst, it transfers data using `INCR` (undefined length) and `SINGLE` transactions.

The receive DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in MTL receive FIFO buffer or when the end of frame (when it is less than the configured burst length) is detected in the receive FIFO buffer. The DMA indicates the start address and the number of transfers required to the master interface. When the interface is configured for fixed-length burst, it transfers data using the best combination of `INCR4`, 8, or 16 and `SINGLE` transactions. If the end-of-frame is reached before the fixed burst ends on the interface, then dummy transfers are performed in order to complete the fixed burst. If the `FB` bit of Register 0 (`Bus Mode Register`) is clear, it transfers data using `INCR` (undefined length) and `SINGLE` transactions.

When the interface is configured for address aligned words, both DMA engines ensure that the first burst transfer initiated is less than or equal to the size of the configured packet burst length. Thus, all subsequent beats start at an address that is aligned to the configured packet burst length. The DMA can only align the address for beats up to size 16 (for `PBL` > 16), because the interface does not support more than `INCR16`.

Host Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame. The software driver should discard the dummy bytes based on the start address of the buffer and size of the frame.[†]

Example: Buffer Read

If the transmit buffer address is 0x0000FF2, and 15 bytes must be transferred, then the DMA reads five full words from address 0x0000FF0, but when transferring data to the MTL transmit FIFO buffer, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are

also ignored. The DMA always ensures it transfers data in 32-bit increments to the MTL transmit FIFO buffer, unless it is the end-of-frame.

Example: Buffer Write

If the receive buffer address is 0x0000FF2 and 16 bytes of a received frame must be transferred, then the DMA writes 3 full words from address 0x0000FF0. But the first 2 bytes of first transfer and the last 2 bytes of the fourth transfer have dummy data.

Buffer Size Calculations

The DMA does not update the size fields in the transmit and receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver must perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by the buffer size field of TDES1) to the MAC. If a descriptor is marked as the first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as the last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of-frame to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or the end-of-frame is received from the MTL. If a descriptor is not marked as the last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as the last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the data width of system bus, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the receive descriptor to have a 0x1002 offset. The receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

Transmission

The DMA can transmit with or without an optional second frame (OSF).

Related Information

[Transmit Descriptor](#) on page 17-27

TX DMA Operation: Default (Non-OSF) Mode

The transmit DMA engine in default mode proceeds as follows: †

1. The Host sets up the transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet frame data. †
2. When Bit 13 (ST) of Register 6 (Operation Mode Register) is set, the DMA enters the Run state. †
3. While in the Run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the Host (TDES0[31] = 0), or if an error condition occurs, transmission is suspended and both the Bit 2 (Transmit Buffer Unavailable) and Bit 16

(Normal Interrupt Summary) of the Register 5 (Status Register) are set. The transmit Engine proceeds to **step 9**.

4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1), the DMA decodes the transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the transmit data from the Host memory and transfers the data to the MTL for transmission. †
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Repeat **step 3**, **step 4**, and **step 5** until the end-of-Ethernet-frame data is transferred to the MTL. †
7. When frame transmission is complete, if IEEE 1588 timestamping was enabled for the frame (as indicated in the transmit status) the timestamp value obtained from MTL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the Own bit is cleared during this step, the Host now owns this descriptor. If timestamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3. †
8. Bit 0 (Transmit Interrupt) of Register 5 (Status Register) is set after completing transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its Last descriptor. The DMA engine then returns to **step 3**. †
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to **step 3**) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. †

Figure 17-6: TX DMA Operation in Default Mode

Related Information

TX DMA Operation: Default (Non-OSF) Mode on page 17-17

TX DMA Operation: OSF Mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first [if Bit 2 (OSF) in Register 6 (Operation Mode Register) is set]. As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second

frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information. †

In OSF mode, the Run state transmit DMA operates in the following sequence: †

1. The DMA operates as described in steps 1 - 6 of the **TX DMA Operation: Default (Non-OSF) Mode** on page 17-17 section.
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor. †
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to **step 7**. †
4. The DMA fetches the transmit frame from the Host memory and transfers the frame to the MTL until the End-of-frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors. †
5. The DMA waits for the previous frame's frame transmission status and timestamp. Once the status is available, the DMA writes the timestamp to TDES2 and TDES3, if such timestamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared Own bit, to the corresponding TDES0, thus closing the descriptor. If timestamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3. †
6. If enabled, the transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to **step 3** (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (**step 7**). †
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA writes the timestamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode. †
8. The DMA can exit Suspend mode and enter the Run state (go to **step 1** or **step 2** depending on pending status) only after receiving a Transmit Poll demand (Register 1 (Transmit Poll Demand Register)). †

Note: As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than two different descriptors for correct and proper operation. †

Figure 17-7: TX DMA Operation in OSF Mode

Transmit Frame Processing

The transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields and that the DA, SA, and Type/Len fields contain valid data. If the transmit descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. †

Frames can be datachained and can span several buffers. Frames must be delimited by the First Descriptor (TDES1[29]) and the Last Descriptor (TDES1[30]), respectively. †

As transmission starts, the First Descriptor must have (TDES1[29]) set. When this occurs, frame data transfers from the Host buffer to the MTL transmit FIFO buffer. Concurrently, if the current frame has the Last Descriptor (TDES1[30]) clear, the transmit Process attempts to acquire the Next descriptor. The transmit Process expects this descriptor to have TDES1[29] clear. If TDES1[30] is clear, it indicates an intermediary buffer. If TDES1[30] is set, it indicates the last buffer of the frame. †

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 0 (TDES0) word of the descriptor that has the last segment set in Transmit Descriptor 1 (TDES1[30]). At this time, if Interrupt on Completion (TDES1[31]) is set, the Bit 0 (Transmit Interrupt) of Register 5 (Status Register) is set, the Next descriptor is fetched, and the process repeats. †

The actual frame transmission begins after the MTL transmit FIFO buffer has reached either a programmable transmit threshold (Bits [16:14] of Register 6 (Operation Mode Register)), or a full frame is contained in the FIFO buffer. There is also an option for Store and Forward Mode (Bit 21 of Register 6 (Operation Mode Register)). Descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the frame. †

Note: To ensure proper transmission of a frame and the next frame, you must specify a non-zero buffer size for the transmit descriptor that has the Last Descriptor (TDES1[30]) set. †

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions: †

- The DMA detects a descriptor owned by the Host (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command. †
- A frame transmission is aborted when a transmit error because of underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set. †

If the DMA goes into SUSPEND state because of the first condition, then both Bit 16 (Normal Interrupt Summary) and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) are set. If the second condition occur, both Bit 15 (Abnormal Interrupt Summary) and Bit 5 (Transmit Underflow) of Register 5 (Status Register) are set, and the information is written to Transmit Descriptor 0, causing the suspension. †

In both cases, the position in the transmit List is retained. The retained position is that of the descriptor following the Last descriptor closed by the DMA. †

The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause. †

Reception

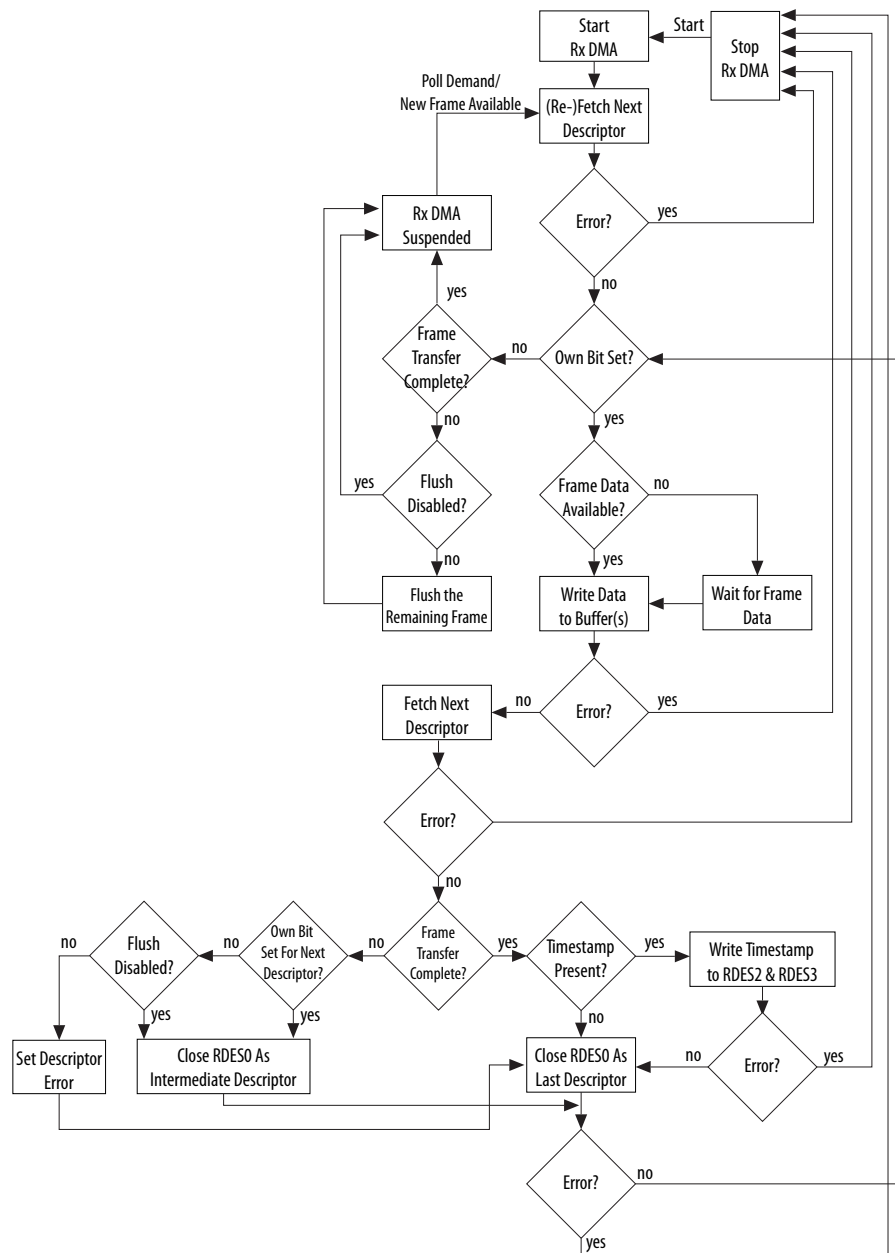

Receive functions use receive descriptors.

The receive DMA engine's reception sequence is proceeds as follows:

1. The host sets up receive descriptors (RDES0-RDES3) and sets the Own bit (RDES0[31]).†
2. When Bit 1 (SR) of Register 6 (Operation Mode Register) is set, the DMA enters the Run state. While in the Run state, the DMA polls the receive descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the host), the DMA enters the Suspend state and jumps to [step 9](#).†
3. The DMA decodes the receive data buffer address from the acquired descriptors.†
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.†
5. When the buffer is full or the frame transfer is complete, the receive engine fetches the next descriptor.†

6. If the current frame transfer is complete, the DMA proceeds to [step 7](#). If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled in Bit 24 of Register 6 (Operation Mode Register)). The DMA closes the current descriptor (clears the Own bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to [step 8](#). If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to [step 4](#).[†]
7. If IEEE 1588 timestamping is enabled, the DMA writes the timestamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the receive frame's status from the MTL and writes the status word to the current descriptor's RDES0, with the Own bit cleared and the Last Segment bit set.[†]
8. The receive engine checks the latest descriptor's Own bit. If the host owns the descriptor (Own bit is 0), the Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set and the DMA receive engine enters the Suspended state (Step 9). If the DMA owns the descriptor, the engine returns to [step 4](#) and awaits the next frame.
9. Before the receive engine enters the Suspend state, partial frames are flushed from the receive FIFO buffer. You can control flushing using Bit 24 of Register 6 (Operation Mode Register).[†]
10. The receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the MTL's receive FIFO buffer. The engine proceeds to [step 2](#) and refetches the next descriptor.[†]

Figure 17-8: Receive DMA Operation

When software has enabled timestamping through the `tsena` bit of register 448 (Timestamp Control Register) and a valid timestamp value is not available for the frame (for example, because the receive FIFO buffer was full before the timestamp could be written to it), the DMA writes all ones to RDES2 and RDES3 descriptors. Otherwise (that is, if timestamping is not enabled), the RDES2 and RDES3 descriptors remain unchanged.

Related Information

Receive Descriptor

Receive Descriptor Acquisition

The receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied: †

- Bit 1 (Start or Stop Receive) of Register 6 (Operation Mode Register) has been set immediately after being placed in the Run state. †
- The data buffer of the current descriptor is full before the frame ends for the current transfer. †
- The controller has completed frame reception, but the current receive descriptor is not yet closed. †
- The receive process has been suspended because of a host-owned buffer (RDES0[31] = 0) and a new frame is received. †
- A Receive poll demand has been issued. †

Receive Frame Processing

The MAC transfers the received frames to the Host memory only when the frame passes the address filter and frame size is greater than or equal to the configurable threshold bytes set for the receive FIFO buffer of MTL, or when the complete frame is written to the FIFO buffer in store-and-forward mode. †

If the frame fails the address filtering, it is dropped in the MAC block itself (unless Bit 31 (Receive All) of Register 1 (MAC Frame Filter) is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be removed from the MTL receive FIFO buffer. †

After 64 (configurable threshold) bytes have been received, the MTL block requests the DMA block to begin transferring the frame data to the receive buffer pointed by the current descriptor. The DMA sets the First Descriptor (RDES0[9]) after the DMA Host interface becomes ready to receive a data transfer (if the DMA is not fetching transmit data from the host), to delimit the frame. The descriptors are released when the Own (RDES[31]) bit is clear, either as the Data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (RDES[8]) and First Descriptor (RDES[9]) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets bit 6 (Receive Interrupt) of Register 5 (Status Register). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs, Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set and the receive process enters the Suspend state. The position in the receive list is retained. †

Receive Process Suspended

If a new receive frame arrives while the receive process is in the suspend state, the DMA refetches the current descriptor in the Host memory. If the descriptor is now owned by the DMA, the receive process re-enters the run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the MTL RX FIFO buffer and increments the missed frame counter. If more than one frame is stored in the MTL EX FIFO buffer, the process repeats. †

The discarding or flushing of the frame at the top of the MTL EX FIFO buffer can be avoided by disabling Flushing (Bit 24 of Register 6 (Operation Mode Register)). In such conditions, the receive process sets the Receive Buffer Unavailable status and returns to the Suspend state. †

Interrupts

Interrupts can be generated as a result of various events. The DMA Register 5 (Status Register) contains a status bit for each of the events that can cause an interrupt. Register 7 (Interrupt Enable Register) contains an enable bit for each of the possible interrupt sources.

There are two groups of interrupts, Normal and Abnormal, as described in Register 5 (Status Register). Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts

within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the `sbd_intr_o` interrupt signal is deasserted. If the MAC is the cause for assertion of the interrupt, then any of the GLI, GMI, GPI, TTI, or GLPII bits of Register 5 (Status Register) are set to 1.

Figure 17-9: Summary Interrupt (`sbd_intr_o`) Generation⁽⁴⁹⁾

Note: Register 5 (Status Register) is the interrupt status register. The interrupt pin (`sbd_intr_o`) is asserted because of any event in this status register only if the corresponding interrupt enable bit is set in Register 7 (Interrupt Enable Register).[†]

Interrupts are not queued, and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Bit 6 (Receive Interrupt) of Register 5 (Status Register) indicates that one or more frames were transferred to the Host buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for multiple, simultaneous events. The driver must scan Register 5 (Status Register) for the cause of the interrupt. After the driver has cleared the appropriate bit in Register 5 (Status Register), the interrupt is not generated again until a new interrupting event occurs. For example, the controller sets Bit 6 (Receive Interrupt) of Register 5 (Status Register) and the driver begins reading Register 5 (Status Register). Next, the interrupt indicated by Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) occurs. The driver clears the receive interrupt (bit 6). However, the `sbd_intr_o` signal is not deasserted, because of the active or pending Receive Buffer Unavailable interrupt.

Bits 7:0 (`riwt` field) of Register 9 (Receive Interrupt Watchdog Timer Register) provide for flexible control of the receive interrupt. When this Interrupt timer is programmed with a non-zero value, it gets activated as soon as the RX DMA completes a transfer of a received frame to system memory without asserting the receive Interrupt because it is not enabled in the corresponding Receive Descriptor (`RDES1[31]`). When this timer runs out as per the programmed value, the `AIS` bit is set and the interrupt is asserted if the corresponding `AIE` is enabled in Register 7 (Interrupt Enable Register). This timer is disabled before it runs out, when a frame is transferred to memory, and the receive interrupt is triggered if it is enabled..

⁽⁴⁹⁾ Signals NIS and AIS are registered.

Error Response to DMA

If the slave replies with an error response to any data transfer initiated by a DMA channel, that DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Register 5 (Status Register). The DMA controller can resume operation only after soft resetting or hard resetting the EMAC and reinitializing the DMA.

Descriptor Overview

The DMA in the Ethernet subsystem transfers data based on a single enhanced descriptor, as explained in the DMA Controller section. The enhanced descriptor is created in the system memory. The descriptor addresses must be word-aligned.

The enhanced or alternate descriptor format can have 8 DWORDS (32 bytes) instead of 4 DWORDS as in the case of the normal descriptor format.

The features of the enhanced or alternate descriptor structure are:

- The alternative descriptor structure is implemented to support buffers of up to 8 KB (useful for Jumbo frames).[†]
- There is a re-assignment of control and status bits in TDES0, TDES1, RDES0 (advanced timestamp or IPC full offload configuration), and RDES1.[†]
- The transmit descriptor stores the timestamp in TDES6 and TDES7 when you select the advanced timestamp.[†]
- The receive descriptor structure is also used for storing the extended status (RDES4) and timestamp (RDES6 and RDES7) when advanced timestamp, IPC Full Checksum Offload Engine, or Layer 3 and Layer 4 filter feature is selected.[†]
- You can select one of the following options for descriptor structure:
 - If timestamping is enabled in Register 448 (Timestamp Control Register) or Checksum Offload is enabled in Register 0 (MAC Configuration Register), the software must to allocate 32 bytes (8 DWORDS) of memory for every descriptor by setting Bit 7 (Descriptor Size) of Register 0 (Bus Mode Register).
 - If timestamping or Checksum Offload is not enabled, the extended descriptors (DES4 to DES7) are not required. Therefore, software can use descriptors with the default size of 16 bytes (4 DWORDS) by clearing Bit 7 (Descriptor Size) of Register 0 (Bus Mode Register) to 0.

Detailed bit map of the descriptor structure

Transmit Descriptor

The application software must program the control bits TDES0[31:18] during the transmit descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits except the OWN bit (which it clears) and updates the status bits[7:0].

With the advance timestamp support, the snapshot of the timestamp to be taken can be enabled for a given frame by setting Bit 25 (TTSE) of TDES0. When the descriptor is closed (that is, when the OWN bit is cleared), the timestamp is written into TDES6 and TDES7 as indicated by the status Bit 17 (TTSS) of TDES0.

Note: Only enhanced descriptor formats (4 or 8 DWORDS) are supported.

Note: When the advanced timestamp feature is enabled, software should set Bit 7 of Register 0 (Bus Mode Register), so that the DMA operates with extended descriptor size. When this control bit is clear, the TDES4-TDES7 descriptor space is not valid. †

Table 17-5: Transmit Descriptor Word 0 (TDES0)

Bit	Description
31	<p>OWN: Own Bit</p> <p>When set, this bit indicates that the descriptor is owned by the DMA. When this bit is cleared, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set to avoid a possible race condition between fetching a descriptor and the driver setting an ownership bit. †</p>
30	<p>IC: Interrupt on Completion</p> <p>When set, this bit enables the Transmit Interrupt (Register 5[0]) to be set after the present frame has been transmitted. †</p>
29	<p>LS: Last Segment</p> <p>When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field in TDES1 should have a non-zero value. †</p>
28	<p>FS: First Segment</p> <p>When set, this bit indicates that the buffer contains the first segment of a frame. †</p>
27	<p>DC: Disable CRC</p> <p>When this bit is set, the MAC does not append a CRC to the end of the transmitted frame. This bit is valid only when the first segment (TDES0[28]) is set. †</p>

Bit	Description
26	<p>DP: Disable Pad</p> <p>When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is cleared, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This bit is valid only when the first segment (TDES0[28]) is set. †</p>
25	<p>TTSE: Transmit Timestamp Enable</p> <p>When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set.</p>
24	Reserved
23:22	<p>CIC: Checksum Insertion Control. These bits control the checksum calculation and insertion. The following list describes the bit encoding:</p> <ul style="list-style-type: none"> ▪ 0x0: Checksum insertion disabled. ▪ 0x1: Only IP header checksum calculation and insertion are enabled. ▪ 0x2: IP header checksum and payload checksum calculation and insertion are enabled, but pseudoheader checksum is not calculated in hardware. ▪ 0x3: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudoheader checksum is calculated in hardware. <p>This field is valid when the First Segment control bit (TDES0[28]) is set.</p>
21	<p>TER: Transmit End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring. †</p>
20	<p>TCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a “don’t care” value.</p> <p>TDES0[21] takes precedence over TDES0[20]. †</p>
19:18	<p>LC: Late Collision</p> <p>When set, this bit indicates that frame transmission is aborted because of a collision occurring after the collision window (64-byte times, including preamble, in MII mode and 512-byte times, including preamble and carrier extension, in GMII mode). This bit is not valid if the underflow error bit is set.</p>
17	<p>TTSS: Transmit Timestamp Status</p> <p>This field is used as a status bit to indicate that a timestamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a timestamp value captured for the transmit frame. This field is only valid when the descriptor’s Last Segment control bit (TDES0[29]) is set. †</p>

Bit	Description
16	<p>IHE: IP Header Error</p> <p>When set, this bit indicates that the MAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IPheader version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5. †</p>
15	<p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none">▪ TDES0[14]: Jabber Timeout▪ TDES0[13]: Frame Flush▪ TDES0[11]: Loss of Carrier▪ TDES0[10]: No Carrier▪ TDES0[9]: Late Collision▪ TDES0[8]: Excessive Collision▪ TDES0[2]: Excessive Deferral▪ TDES0[1]: Underflow Error▪ TDES0[16]: IP Header Error▪ TDES0[12]: IP Payload Error †
14	<p>JT: Jabber Timeout</p> <p>When set, this bit indicates the MAC transmitter has experienced a jabber time-out. This bit is only set when Bit 22 (Jabber Disable) of Register 0 (MAC Configuration Register) is not set. †</p>
13	<p>FF: Frame Flushed</p> <p>When set, this bit indicates that the DMA or MTL flushed the frame because of a software Flush command given by the CPU. †</p>
12	<p>IPE: IP Payload Error</p> <p>When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch. †</p>

Bit	Description
11	<p>LC: Loss of Carrier</p> <p>When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the <code>gmii_crs_i</code> signal was inactive for one or more transmit clock periods during frame transmission). This bit is valid only for the frames transmitted without collision when the MAC operates in the half-duplex mode. †</p>
10	<p>NC: No Carrier</p> <p>When set, this bit indicates that the Carrier Sense signal from the PHY was not asserted during transmission. †</p>
9	Reserved
8	<p>EC: Excessive Collision</p> <p>When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If Bit 9 (Disable Retry) in Register 0 (MAC Configuration Register) is set, this bit is set after the first collision, and the transmission of the frame is aborted. †</p>
7	<p>VF: VLAN Frame</p> <p>When set, this bit indicates that the transmitted frame is a VLAN-type frame. †</p>
6:3	<p>CC: Collision Count (Status field)</p> <p>These status bits indicate the number of collisions that occurred before the frame was transmitted. This count is not valid when the Excessive Collisions bit (TDES0[8]) is set. The EMAC updates this status field only in the half-duplex mode.</p>
2	<p>ED: Excessive Deferral</p> <p>When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbps mode or if Jumbo frame is enabled) if Bit 4 (Deferral Check) bit in Register 0 (MAC Configuration Register) is set. †</p>
1	<p>UF: Underflow Error</p> <p>When set, this bit indicates that the MAC aborted the frame because the data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]). †</p>
0	<p>DB: Deferred Bit</p> <p>When set, this bit indicates that the MAC defers before transmission because of the presence of carrier. This bit is valid only in the half-duplex mode. †</p>

Table 17-6: Transmit Descriptor Word 1 (TDES1)

Bit	Description
31:29	Reserved
28:16	TBS2: Transmit Buffer 2 Size This field indicates the second data buffer size in bytes. This field is not valid if TDES0[20] is set. †
15:13	Reserved †
12:0	TBS1: Transmit Buffer 1 Size This field indicates the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]). †

Table 17-7: Transmit Descriptor 2 (TDES2)

Bit	Description
31:09	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. †

Table 17-8: Transmit Descriptor 3 (TDES3)

Bit	Description
31:09	Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.) †

Table 17-9: Transmit Descriptor 6 (TDES6)

Bit	Description
31:09	TTSL: Transmit Frame Timestamp Low This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set. †

Table 17-10: Transmit Descriptor 7 (TDES7)

Bit	Description
31:09	<p>TTSH: Transmit Frame Timestamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set. †</p>

Receive Descriptor

The receive descriptor can have 32 bytes of descriptor data (8 DWORDs) when advanced timestamp or IPC Full Offload feature is selected. When either of these features is enabled, software should set bit 7 of Register 0 (Bus Mode Register) so that the DMA operates with extended descriptor size. When this control bit is clear, the RDES0[0] is always cleared and the RDES4-RDES7 descriptor space is not valid. †

Note: Only enhanced descriptor formats (4 or 8 DWORDS) are supported.

TDES6	Transmit Timestamp Low [31:0]																															
TDES7	Transmit Timestamp High [31:0]																															

Receive Descriptor Field 0 (RDES0)

Table 17-11: Receive Descriptor Field 0 (RDES0)

Bit	Description
31	<p>OWN: Own Bit</p> <p>When set, this bit indicates that the descriptor is owned by the DMA of the EMAC. When this bit is cleared, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.</p>
30	<p>AFM: Destination Address Filter Fail</p> <p>When set, this bit indicates a frame that failed in the DA Filter in the MAC. †</p>
29:16	<p>FL: Frame Length</p> <p>These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are cleared. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame.</p> <p>This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. †</p>
15	<p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: Giant Frame • RDES4[4:3]: IP Header or Payload Error (Receive Descriptor Field 4 (RDES4)) • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error <p>This field is valid only when the Last Descriptor (RDES0[8]) is set. †</p>

Bit	Description
14	<p>DE: Descriptor Error</p> <p>When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next descriptor. The frame is truncated. This bit is valid only when the Last Descriptor (RDES0[8]) bit is set. †</p>
13	<p>SAF: Source Address Filter Fail</p> <p>When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC. †</p>
12	<p>LE: Length Error</p> <p>When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is clear. †</p>
11	<p>OE: Overflow Error</p> <p>When set, this bit indicates that the received frame was damaged because of buffer overflow in MTL.</p> <p>Note: This bit is set only when the DMA transfers a partial frame to the application, which happens only when the RX FIFO buffer is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in the RX FIFO buffer. †</p>
10	<p>VLAN: VLAN Tag</p> <p>When set, this bit indicates that the frame to which this descriptor is pointing is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking the VLAN fields of the received frame based on the Register 7 (VLAN Tag Register) setting. †</p>
9	<p>FS: First Descriptor</p> <p>When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next descriptor contains the beginning of the frame. †</p>
8	<p>LS: Last Descriptor</p> <p>When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame. †</p>

Bit	Description
7	<p>Timestamp Available, IP Checksum Error (Type1), or Giant Frame</p> <p>When the advanced timestamp feature is present, this bit is set to indicate that a snapshot of the Timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This bit is valid only when the Last Descriptor bit (RDES0[8]) is set.</p> <p>When IP Checksum Engine (Type 1) is selected, this bit, is set to indicate that the 16-bit IPv4 Header checksum calculated by the EMAC did not match the received checksum bytes.</p> <p>Otherwise, this bit is set to indicate the Giant frame Status. Giant frames are larger than 1,518-byte (or 1,522-byte for VLAN or 2,000-byte when Bit 27 (2KPE) of MAC Configuration register is set) normal frames and larger than 9,018-byte (9,022-byte for VLAN) frame when Jumbo frame processing is enabled.</p>
6	<p>LC: Late Collision</p> <p>When set, this bit indicates that a late collision has occurred while receiving the frame in the half-duplex mode. †</p>
5	<p>FT: Frame Type</p> <p>When set, this bit indicates that the receive frame is an Ethernet-type frame (the LT field is greater than or equal to 0x0600). When this bit is cleared, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes.</p>
4	<p>RWT: Receive Watchdog Timeout</p> <p>When set, this bit indicates that the receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout. †</p>
3	<p>RE: Receive Error</p> <p>When set, this bit indicates that the <code>gmii_rxr_i</code> signal is asserted while <code>gmii_rxdv_i</code> is asserted during frame reception.</p>
2	<p>DE: Dribble Bit Error</p> <p>When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. †</p>

Bit	Description
1	<p>CE: CRC Error</p> <p>When set, this bit indicates that a CRC error occurred on the received frame. This bit is valid only when the Last Descriptor (RDES0[8]) is set. †</p>
0	<p>Extended Status Available/RX MAC Address</p> <p>When either advanced timestamp or IP Checksum Offload (Type 2) is present, this bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This bit is valid only when the Last Descriptor bit (RDES0[8]) is set.</p> <p>When the Advance Timestamp Feature or IPC Full Offload is not selected, this bit indicates RX MAC Address status. When set, this bit indicates that the RX MAC Address registers value (1 to 15) matched the frame's DA field. When clear, this bit indicates that the RX MAC Address Register 0 value matched the DA field. †</p>

Receive Descriptor Fields (RDES2) and (RDES3)

Receive Descriptor Field 2 (RDES2)

Table 17-13: Receive Descriptor Field 2 (RDES2)

Bit	Description
31:0	<p>Buffer 1 Address Pointer</p> <p>These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the value programmed in RDES2[1:0] for its address generation when the RDES2 value is used to store the start of the frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of the frame but the frame is shifted as per the actual buffer address pointer. The DMA ignores RDES2[1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored. For more information about buffer address alignment, refer to the <i>Host Data Buffer Alignment</i> section.</p>

Related Information

Receive Descriptor Field 4 (RDES4)

The extended status is written only when there is status related to IPC or timestamp available. The availability of extended status is indicated by Bit 0 in RDES0. This status is available only when the Advance Timestamp or IPC Full Offload feature is selected.

Table 17-15: Receive Descriptor Field 4 (RDES4)

Bit	Description
31:28	Reserved †
27:26	<p>Layer 3 and Layer 4 Filter Number Matched</p> <p>These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received frame.</p> <ul style="list-style-type: none"> • 00: Filter 0 • 01: Filter 1 • 10: Filter 2 • 11: Filter 3 <p>This field is valid only when Bit 24 or Bit 25 is set. When more than one filter matches, these bits give only the lowest filter number. †</p>

Bit	Description
25	<p>Layer 4 Filter Match</p> <p>When set, this bit indicates that the received frame matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true:</p> <ul style="list-style-type: none"> • Layer 3 fields are not enabled and all enabled Layer 4 fields match. • All enabled Layer 3 and Layer 4 filter fields match. <p>When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits [27:26].[†]</p>
24	<p>Layer 3 Filter Match</p> <p>When set, this bit indicates that the received frame matches one of the enabled Layer 3 IP Address fields.</p> <p>This status is given only when one of the following conditions is true:</p> <ul style="list-style-type: none"> • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed. • All enabled filter fields match. <p>When more than one filter matches, this bit gives the layer 3 filter status of the filter indicated by Bits [27:26].[†]</p>
23:15	Reserved
14	<p>Timestamp Dropped</p> <p>When set, this bit indicates that the timestamp was captured for this frame but got dropped in the MTL RX FIFO buffer because of overflow.</p>
13	<p>PTP Version</p> <p>When set, this bit indicates that the received PTP message has the IEEE 1588 version 2 format. When clear, it has the version 1 format.</p>
12	<p>PTP Frame Type</p> <p>When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information about IPv4 or IPv6 can be obtained from Bits 6 and 7.</p>

Bit	Description
11:8	<p>Message Type</p> <p>These bits are encoded to give the type of the message received.</p> <ul style="list-style-type: none"> • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011-1110: Reserved • 1111: PTP packet with Reserved message type
7	<p>IPv6 Packet Received</p> <p>When set, this bit indicates that the received packet is an IPv6 packet. This bit is updated only when Bit 10 (IPC) of Register 0 (MAC Configuration Register) is set.</p>
6	<p>IPv4 Packet Received</p> <p>When set, this bit indicates that the received packet is an IPv4 packet. This bit is updated only when Bit 10 (IPC) of Register 0 (MAC Configuration Register) is set.</p>
5	<p>IP Checksum Bypassed</p> <p>When set, this bit indicates that the checksum offload engine is bypassed.</p>
4	<p>IP Payload Error</p> <p>When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the EMAC calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. This bit is valid when either Bit 7 or Bit 6 is set.</p>
3	<p>IP Header Error</p> <p>When set, this bit indicates that either the 16-bit IPv4 header checksum calculated by the EMAC does not match the received checksum bytes, or the IP datagram version is not consistent with the Ethernet Type value. This bit is valid when either Bit 7 or Bit 6 is set.</p>

Bit	Description
2:0	<p>IP Payload Type</p> <p>These bits indicate the type of payload encapsulated in the IP datagram processed by the receive Checksum Offload Engine (COE). The COE also sets these bits to 0 if it does not process the IP datagram's payload due to an IP header error or fragmented IP.</p> <ul style="list-style-type: none"> • 0x0: Unknown or did not process IP payload • 0x1: UDP • 0x2: TCP • 0x3: ICMP • 0x4–0x7: Reserved <p>This bit is valid when either Bit 7 or Bit 6 is set.</p>

IEEE 1588-2002 Timestamps

The IEEE 1588-2002 standard defines the Precision Time Protocol (PTP) that enables precise synchronization of clocks in a distributed network of devices. The PTP applies to systems communicating by local area networks supporting multicast messaging. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. It is frequently used in automation systems where a collection of communicating machines such as robots must be synchronized and hence operate over a common time base.^(†)

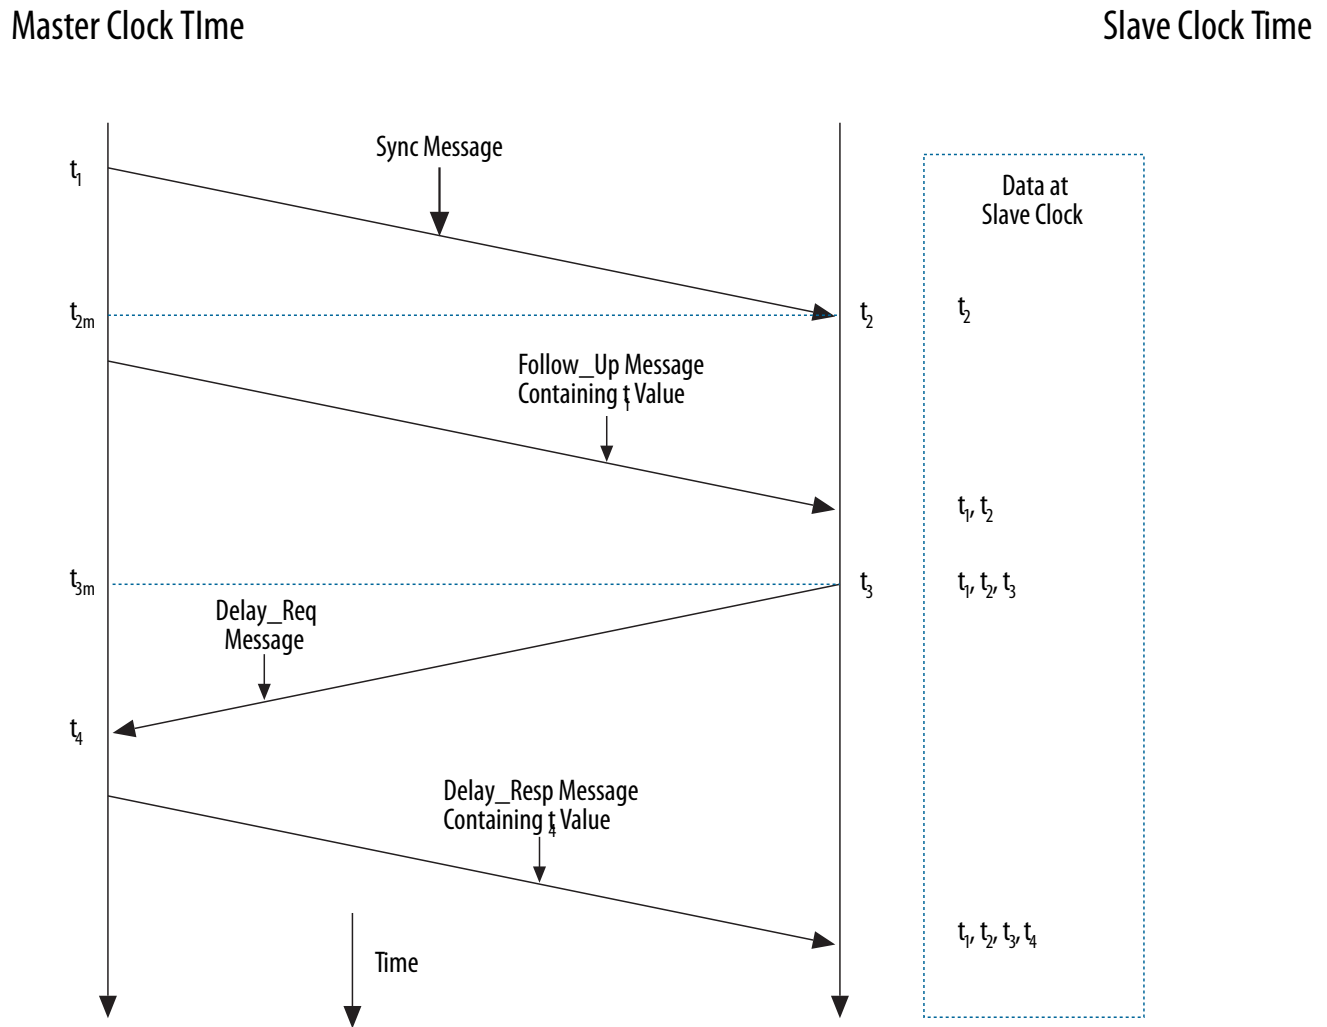

The PTP is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing and clock information.[†]

The following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 17-13: Networked Time Synchronization

The PTP uses the following process for synchronizing a slave node to a master node by exchanging the PTP messages:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t_1 . This time must be captured, for Ethernet ports, at the PHY interface.[†]
2. The slave receives the sync message and also captures the exact time, t_2 , using its timing reference.[†]
3. The master sends a follow_up message to the slave, which contains t_1 information for later use.[†]
4. The slave sends a delay_req message to the master, noting the exact time, t_3 , at which this frame leaves the PHY interface.[†]
5. The master receives the message, capturing the exact time, t_4 , at which it enters its system.[†]
6. The master sends the t_4 information to the slave in the delay_resp message.[†]
7. The slave uses the four values of t_1 , t_2 , t_3 , and t_4 to synchronize its local timing reference to the master's timing reference.[†]

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at

the PHY interface. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.[†]

The EMAC is intended to support IEEE 1588 operation in all modes with a resolution of 1 microsecond. When the two EMACs are operating in an IEEE 1588 environment, the MPU subsystem is responsible for maintaining synchronization between the time counters internal to the two MACs.

The IEEE 1588 interface to the FPGA allows the FPGA to provide a source for the `emac_ptp_ref_clk` input as well to allow it to monitor the pulse per second output from each EMAC controller.

The EMAC component provides a hardware assisted implementation of the IEEE 1588 protocol. Hardware support is for timestamp maintenance. Timestamps are updated when receiving any frame on the PHY interface, and the receive descriptor is updated with this value. Timestamps are also updated when the SFD of a frame is transmitted and the transmit descriptor is updated accordingly.[†]

For details about the IEEE 1588-2002 standard, refer to IEEE Standard 1588-2002 - IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, available on the IEEE Standards Association website.[†]

Reference Timing Source

To get a snapshot of the time, the EMAC takes the reference clock input and uses it to generate the reference time (64-bit) internally and capture timestamps.[†]

System Time Register Module

The 64-bit time is maintained in this module and updated using the input reference clock, `clk_ptp_ref`, which can be the `emac_ptp_clk` from the HPS or the `f2s_ptp_ref_clk` from the FPGA. The `emac_ptp_clk` in the HPS is a derivative of the `osc1_clk` and is configured in the clock manager. This input reference clock is the source for taking snapshots (timestamps) of Ethernet frames being transmitted or received at the PHY interface.

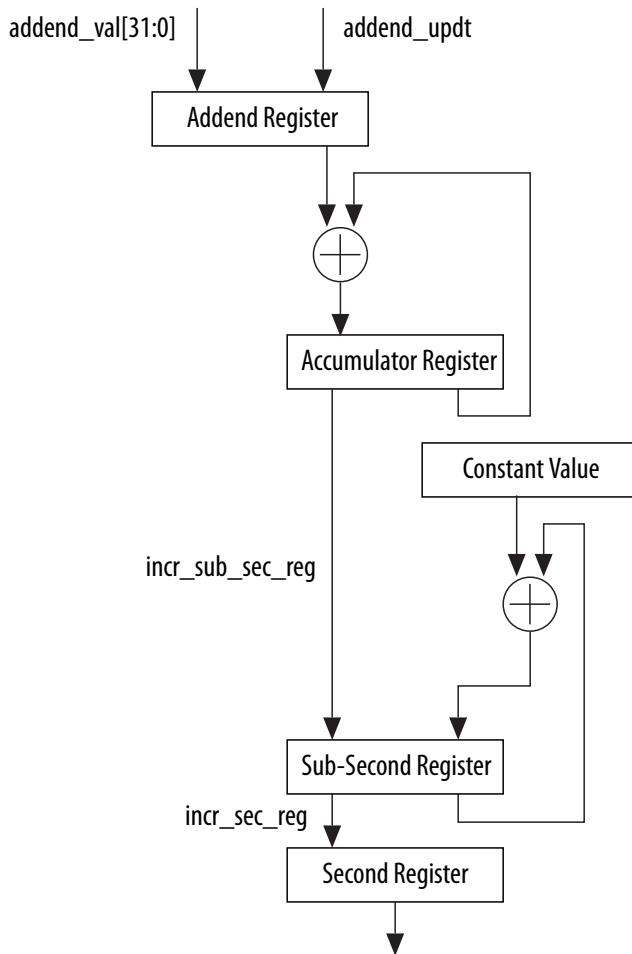

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, each EMAC's system time counter is written with the value in the Timestamp Update registers, while for system time correction, the offset value is added to or subtracted from the system time.

With the fine correction method, a slave clock's frequency drift with respect to the master clock is corrected over a period of time instead of in one clock, as in coarse correction. This protocol helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals.[†]

With this method, an accumulator sums up the contents of the Timestamp_Addend register, as shown in the figure below. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.[†]

Figure 17-14: Algorithm for System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division ratio (FreqDivisionRatio) is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (`clk_ptp_ref_i`) is for example, 66 MHz, this ratio is calculated as $66 \text{ MHz} / 50 \text{ MHz} = 1.32$. Hence, the default addend value to program in the register is $232 / 1.32$, 0xC1F07C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is $65 / 50$, or 1.3 and the value to set in the addend register is $232 / 1.30$, or 0xC4EC4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F ($232 / 1.32$) must be programmed.[†]

In the above figure, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.†

Initially, the slave clock is set with `FreqCompensationValue0` in the Addend register. This value is as follows:†

$$\text{FreqCompensationValue}_0 = 232 / \text{FreqDivisionRatio}^\dagger$$

If `MasterToSlaveDelay` is initially assumed to be the same for consecutive sync messages, the algorithm described below must be applied. After a few sync cycles, frequency lock occurs. The slave clock can then determine a precise `MasterToSlaveDelay` value and re-synchronize with the master using the new value.†

The algorithm is as follows:†

- At time `MasterSyncTimen` the master sends the slave clock a sync message. The slave receives this message when its local clock is `SlaveClockTimen` and computes `MasterClockTimen` as:†

$$\text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n^\dagger$$

- The master clock count for current sync cycle, `MasterClockCountn` is given by:†

$$\text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}^\dagger$$

(assuming that `MasterToSlaveDelay` is the same for sync cycles n and $n - 1$)†

- The slave clock count for current sync cycle, `SlaveClockCountn` is given by:†

$$\text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}^\dagger$$

- The difference between master and slave clock counts for current sync cycle, `ClockDiffCountn` is given by:†

$$\text{ClockDiffCount}_n = \text{MasterClockCount}_n - \text{SlaveClockCount}_n^\dagger$$

- The frequency-scaling factor for the slave clock, `FreqScaleFactorn` is given by:†

$$\text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n^\dagger$$

- The frequency compensation value for Addend register, `FreqCompensationValuen` is given by: †

$$\text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n \times \text{FreqCompensationValue}_{n-1} - 1^\dagger$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions.†

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.†

Transmit Path Functions

The MAC captures a timestamp when the start-of-frame data (SFD) is sent on the PHY interface. You can control the frames for which timestamps are captured on a per frame basis. In other words, each transmit frame can be marked to indicate whether a timestamp should be captured for that frame. †

You can use the control bits in the transmit descriptor to indicate whether a timestamp should be captured for a frame. The MAC returns the timestamp to the software inside the corresponding transmit descriptor, thus connecting the timestamp automatically to the specific PTP frame. The 64-bit timestamp information is written to the TDES2 and TDES3 fields. †

Receive Path Functions

The MAC captures the timestamp of all frames received on the PHY interface. The DMA returns the timestamp to the software in the corresponding receive descriptor. The timestamp is written only to the last receive descriptor. †

Timestamp Error Margin

According to the IEEE1588 specifications, a timestamp must be captured at the SFD of the transmitted and received frames at the PHY interface. Because the PHY interface receive and transmit clocks are not synchronous to the reference timestamp clock (`clk_ptp_ref`) a small amount of drift is introduced when a timestamp is moved between asynchronous clock domains. In the transmit path, the captured and reported timestamp has a maximum error margin of two PTP clocks, meaning that the captured timestamp has a reference timing source value that is occurred within two clocks after the SFD is transmitted on the PHY interface.

Similarly, in the receive path, the error margin is three PHY interface clocks, plus up to two PTP clocks. You can ignore the error margin due to the PHY interface clock by assuming that this constant delay is present in the system (or link) before the SFD data reaches the PHY interface of the MAC. †

Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the EMAC clock domain to the FPGA clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is four PHY interface clock cycles and three PTP clock cycles. If the delay between two timestamp captures is less than this amount, the MAC does not take a timestamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (20 ns resulting in 50 MHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance. †

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the PHY interface clock frequency is fixed by the IEEE 1588 specification, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC. †

Table 17-18: Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency
100-Mbps full-duplex operation	168 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 16 clocks of preamble)	$(3 * \text{PTP}) + (4 * \text{MII}) \leq 168 * \text{MII}$, that is, $\sim 0.5 \text{ MHz}$ $(168 - 4) * 40 \text{ ns} \div 3 = 2180 \text{ ns period}$
1000-Mbps half duplex operation	24 GMII clocks (4 for a jam pattern sent just after SFD because of collision + 12 IFG + 8 preamble)	$(3 * \text{PTP}) + 4 * \text{GMII} \leq 24 * \text{GMII}$, that is, 18.75 MHz

Related Information

IEEE 1588-2008 Advanced Timestamps

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the EMAC supports the following advanced timestamp features defined in the IEEE 1588-2008 standard.[†]

- Supports the IEEE 1588-2008 (version 2) timestamp format.[†]
- Provides an option to take a timestamp of all frames or only PTP-type frames.[†]
- Provides an option to take a timestamp of event messages only.[†]
- Provides an option to take the timestamp based on the clock type: ordinary, boundary, end-to-end, or peer-to-peer.[†]
- Provides an option to configure the EMAC to be a master or slave for ordinary and boundary clock.[†]
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.[†]
- Provides an option to measure sub-second time in digital or binary format.[†]

Related Information

<http://standards.ieee.org/findstds/index.html>

For more information about advanced timestamp features, refer to the *IEEE Standard 1588 - 2008 IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control System*, available on the IEEE Standards Association website.

Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) messages in addition to SYNC, Delay Request, Follow-up, and Delay Response messages.[†]

Clock Types

The EMAC supports the following clock types defined in the IEEE 1588-2008 standard:

- Ordinary clock[†]
- Boundary clock[†]
- End-to-End transparent clock[†]
- Peer-to-Peer transparent clock[†]

Reference Timing Source

The EMAC supports the following reference timing source features defined in the IEEE 1588-2008 standard:

- 48-bit seconds field[†]
- Fixed pulse-per-second output[†]
- Flexible pulse-per-second output[†]
- Auxiliary snapshots (timestamps) with external events

Transmit Path Functions

The advanced timestamp feature is supported through the descriptors format.

Receive Path Functions

The MAC processes the received frames to identify valid PTP frames. You can control the snapshot of the time to be sent to the application, by using the following options:[†]

- Enable timestamp for all frames.[†]
- Enable timestamp for IEEE 1588 version 2 or version 1 timestamp.[†]
- Enable timestamp for PTP frames transmitted directly over Ethernet or UDP/IP Ethernet.[†]
- Enable timestamp snapshot for the received frame for IPv4 or IPv6.[†]
- Enable timestamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP) only.[†]
- Enable the node to be a master or slave and select the timestamp type to control the type of messages for which timestamps are taken.[†]

The DMA returns the timestamp to the software inside the corresponding transmit or receive descriptor.

Auxiliary Snapshot

The auxiliary snapshot feature allows you to store a snapshot (timestamp) of the system time based on an external event. The event is considered to be the rising edge of the sideband signal `ptp_aux_ts_trig_i` from the FPGA. One auxiliary snapshot input is available. The depth of the auxiliary snapshot FIFO buffer is 16.

The timestamps taken for any input are stored in a common FIFO buffer. The host can read Register 458 (Timestamp Status Register) to know which input's timestamp is available for reading at the top of this FIFO buffer.

Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from Register 457 (System Time - Higher Word Seconds Register) when it is present. When a snapshot is stored, the MAC indicates this to the host with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status (`ATSSTM`) is set in Register 458 (Timestamp Status Register). This indicates that the latest auxiliary snapshot of the timestamp was not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full. When a host reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting Bit 19

(*ATSFC*) in Register 448 (Timestamp Control Register). When multiple snapshots are present in the FIFO, the count is indicated in Bits [27:25], *ATSNS*, of Register 458 (Timestamp Status Register).[†]

IEEE 802.3az Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) standardized by IEEE 802.3-az, version D2.0 is supported by the EMAC. It is supported by the MAC operating in 10/100/1000 Mbps rates. EEE is only supported when the EMAC is configured to operate with the RGMII PHY interface operating in full-duplex mode. It cannot be used in half-duplex mode.

EEE enables the MAC to operate in Low-Power Idle (LPI) mode. Either end point of an Ethernet link can disable functionality to save power during periods of low link utilization. The MAC controls whether the system should enter or exit LPI mode and communicates this information to the PHY.[†]

Related Information

<http://www.ieee802.org/3/>

For details about the *IEEE 802.3az Energy Efficient Ethernet standard*, refer to the IEEE 802.3 Ethernet Working Group website.[†]

LPI Timers

Two timers internal to the EMAC are associated with LPI mode:

- LPI Link Status (LS) Timer[†]
- LPI Time Wait (TW) Timer[†]

The LPI LS timer counts, in ms, the time expired since the link status has come up. This timer is cleared every time the link goes down and is incremented when the link is up again and the terminal count as programmed by the software is reached. The PHY interface does not assert the LPI pattern unless the terminal count is reached. This protocol ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as one second in the IEEE standard 802.3-az, version D2.0. The LPI LS timer is 10 bits wide, so the software can program up to 1023 ms.[†]

The LPI TW timer counts, in μ s, the time expired since the deassertion of LPI. The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. The LPI TW timer is 16 bits wide, so the software can program up to 65535 μ s.[†]

The EMAC generates the LPI interrupt when the transmit or receive channel enters or exits the LPI state.[†]

Checksum Offload

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the EMAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path.

Supported offloading types:

- Transmit IP header checksum[†]
- Transmit TCP/UDP/ICMP checksum[†]
- Receive IP header checksum[†]
- Receive full checksum[†]

Frame Filtering

The EMAC implements the following types of filtering for receive frames.

Source Address or Destination Address Filtering

The Address Filtering Module checks the destination and source address field of each incoming packet.[†]

Unicast Destination Address Filter

Up to 128 MAC addresses for unicast perfect filtering are supported. The filter compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr127 are selected with an individual enable bit. For MacAddr1–MacAddr31 addresses, you can mask each byte during comparison with the corresponding received DA byte. This enables group address filtering for the DA. The MacAddr32–MacAddr127 addresses do not have mask control and all six bytes of the MAC address are compared with the received six bytes of DA.[†]

In hash filtering mode, the filter performs imperfect filtering for unicast addresses using a 256-bit hash table. It uses the upper ten bits of the CRC of the received destination address to index the content of the hash table. A value of 0 selects Bit 0 of the selected register, and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, the unicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.[†]

Multicast Destination Address Filter

The MAC can be programmed to pass all multicast frames. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported. In hash filtering mode, the filter performs imperfect filtering using a 256-bit hash table. For hash filtering, it uses the upper ten bits of the CRC of the received multicast address to index the contents of the hash table. A value of 0 selects Bit 0 of the selected register and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, then the multicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.[†]

Hash or Perfect Address Filter

The filter can be configured to pass a frame when its DA matches either the hash filter or the Perfect filter. This configuration applies to both unicast and multicast frames.[†]

Broadcast Address Filter

The filter does not filter any broadcast frames in the default mode. However, if the MAC is programmed to reject all broadcast frames, the filter drops any broadcast frame.[†]

Unicast Source Address Filter

The MAC can also perform a perfect filtering based on the source address field of the received frames. Group filtering with SA is also supported. You can filter a group of addresses by masking one or more bytes of the address.[†]

Inverse Filtering Operation (Invert the Filter Match Result at Final Output)

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. The result of the unicast or multicast destination address filter is inverted in this mode.[†]

Destination and Source Address Filtering Summary

The tables below summarize the destination and source address filtering based on the type of frames received and the configuration of bits within the Mac_Frame_Filter register.†

Table 17-19: Destination Address Filtering†

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	Destination Address Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all frames
	X	X	X	X	X	1	X	Pass all frames
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause frames if PCF= 0X
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause frames if PCF = 0X
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause frames if PCF = 0X
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause frames if PCF=0X
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Paus frames if PCF = 0X
	0	1	X	1	1	0	X	Fail Hash on Perfect/Group filter match and drop Pause frames if PCF = 0X

Table 17-20: Source Address Filtering[†]

Frame Type	PR	DAIF	DBF	Source Address Filter Operation
Unicast	1	X	X	Pass all frames
	0	0	0	Pass status on Perfect or Group filter match but do not drop frames that fail.
	0	1	0	Fail on Perfect or Group filter match but do not drop frame
	0	0	1	Pass on Perfect or Group filter match and drop frames that fail
	0	1	1	Fail on Perfect or Group filter match and drop frames that fail

VLAN Filtering

The EMAC supports the two kinds of VLAN filtering:

- VLAN tag-based filtering[†]
- VLAN hash filtering[†]

VLAN Tag-Based Filtering

In the VLAN tag-based frame filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status and drops the VLAN frames that do not match. You can also enable the inverse matching for VLAN frames. In addition, you can enable matching of SVLAN tagged frames along with the default Customer Virtual Local Area Network (C-VLAN) tagged frames.[†]

VLAN Hash Filtering with a 16-Bit Hash Table

The MAC provides VLAN hash filtering with a 16-bit hash table. The MAC also supports the inverse matching of the VLAN frames. In inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a frame is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.[†]

Layer 3 and Layer 4 Filters

Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering. The frames are filtered in the following ways:[†]

- Matched frames[†]
- Unmatched frames[†]
- Non-TCP or UDP IP frames[†]

Matched Frames

The MAC forwards the frames, which match all enabled fields, to the application along with the status. The MAC gives the matched field status only if one of the following conditions is true:[†]

- All enabled Layer 3 and Layer 4 fields match.[†]
- At least one of the enabled field matches and other fields are bypassed or disabled.[†]

Using the CSR set, you can define up to four filters, identified as filter 0 through filter 3. When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides status of the lowest filter with filter 0 being the lowest and filter 3 being the highest. For example, if filter 0 and filter 1 match, the MAC gives the status corresponding to filter 0.[†]

Unmatched Frames

The MAC drops the frames that do not match any of the enabled fields. You can use the inverse match feature to block or drop a frame with specific TCP or UDP over IP fields and forward all other frames. You can configure the EMAC so that when a frame is dropped, it receives a partial frame with appropriate abort status or drops it completely.[†]

NonTCP or UDP IP Frames

By default, all non-TCP or UDP IP frames are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP frames.[†]

Clocks and Resets

Clock Structure

The Ethernet Controller received five input clocks and generates one output clock.

The EMAC controller provides the clock division and muxing necessary to generate the proper clocks for each of the PHY modes and data rates. The clock domains to the Ethernet controller are as follows

- l4_mp_clk clock
- EMAC RX clock
- EMAC TX clock
- clk_ptp_ref

The diagram below summarizes the clock domains of the EMAC module:

Figure 17-15: EMAC Clock Diagram

Clock Gating for EEE

For the RGMII PHY interface, you can gate the transmit clock for Energy Efficient Ethernet (EEE) applications.

Related Information

[Programming Guidelines for Energy Efficient Ethernet](#) on page 17-63

Reset

The EMAC module accepts a single reset input, `emac_rst_n`, which is active low.

Note: In all modes, the EMAC core depends on the PHY clocks to be active for the internal EMAC clock sources to be valid.

Taking the Ethernet MAC Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

Interrupts are generated as a result of specific events in the EMAC and external PHY device. The interrupt status register indicates all conditions which may trigger an interrupt and the interrupt enable register determines which interrupts can propagate.

Ethernet MAC Programming Model

The initialization and configuration of the EMAC and its interface is a multi-step process that includes system register programming in the System Manager and Clock Manager and configuration of clocks in multiple domains.

Note: When the EMAC interfaces to HPS I/O and register content is being transferred to a different clock domain after a write operation, no further writes should occur to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Thus, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).[†] If the CSR is accessed multiple times quickly, you must ensure that a minimum number of destination clock cycles have occurred between accesses.

Note: When using the EMAC with signals routed through the FPGA fabric, the minimum time required between two write accesses to the same register is 10 TX clock cycles.

System Level EMAC Configuration Registers

In addition to the registers in the Ethernet Controller, there are other system level registers in the Clock Manager, System Manager and Reset Manager that must be programmed in order to configure the EMAC and its interfaces.

The following table gives a summary of the important System Manager clock register bits that control operation of the EMAC. These register bits are static signals that must be set while the corresponding EMAC is in reset.

Table 17-21: System Manager Clock and Interface Settings

Register.Field	Description
ctrl.ptpclkssel_0 ctrl.ptpclkssel_1	1588 PTP reference clock. This bit selects the source of the 1588 PTP reference clock. <ul style="list-style-type: none"> 0x0= osc1_clk (default from Clock Manager) 0x1= fpga_ptp_ref_clk (from FPGA fabric; in this case, the FPGA must be in usermode with an active reference clock)
ctrl.physel_0 ctrl.physel_1	PHY Interface Select. These two bits set the PHY mode. <ul style="list-style-type: none"> 0x0= GMII or MII 0x1= RGMII 0x2= RMII (default) <p>Note: Selecting the 0x0 encoding routes the GMII/MII signals to the FPGA fabric only and selecting the 0x1 encoding routes the RGMII signals to the HPS only.</p>

The following table summarizes the important System Manager configuration register bits. All of the fields, except the AXI cache settings, are assumed to be static and must be set before the EMAC is brought out of reset. If the FPGA interface is used, the FPGA must be in user mode and enabled with the appropriate clock signals active before the EMAC can be brought out of reset.

Table 17-22: System Manager Static Control Settings

Register.Field	Description
module.emac_0 module.emac_1	FPGA interface to EMAC disable. This field is used to disable signals from the FPGA to the EMAC modules that could potentially interfere with their normal operation <ul style="list-style-type: none"> • 0x0= Disable (default) • 0x1=Enable
l3master.awcache_1 l3master.awcache_0 l3master.arcache_1 l3master.arcache_0	EMAC AXI Master AxCACHE settings. It is recommended that these bits are set while the EMAC is idle or in reset.

Various registers within the Clock Manager must also be configured in order for the EMAC controller to perform properly.

Table 17-23: Clock Manager Settings

Register.Field	Description
emac0clk.cnt emac1clk.cnt	EMAC clock control. The cnt value in this register is used to divide the PLL VCO frequency to generate emac0clk and emac1clk.
en.emac0clk en.emac1clk	emac0clk and emac1clk output enable.

EMAC FPGA Interface Initialization

To initialize the Ethernet controller to use the FPGA GMII/MII interface, specific software steps must be followed.

In general, the FPGA interface must be active in user mode with valid PHY clocks, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate emac bit in the permodrst register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate cnt value in the emac*clk register in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. If the PTP clock source is from the FPGA, ensure that the FPGA f2s_ptp_ref_clk is active.

5. The soft GMII/MII adaptor must be loaded with active clocks propagating. The FPGA must be configured to user mode and a reset to the user soft FPGA IP may be required to propagate the PHY clocks to the HPS.
6. Once all clock sources are valid, apply the following clock settings:
 - a. Program the `physe1_*` field in the `ctrl` register of the System Manager (EMAC Group) to 0x0 to select the GMII/MII PHY interface.
 - b. If the PTP clock source is from the FPGA, set the `ptpclkse1_*` bit in the `ctrl` register (EMAC group) of the System Manager to be 0x1.
 - c. Enable the Ethernet Controller FPGA interface by setting the `emac_*` bit in the `module` register of the System Manager (FPGA Interface group).
7. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include AXI AxCache signal values which are programmed in `l3_register` in the EMAC group of the System Manager.
8. Execute a register read back to confirm the clock and static configuration settings are valid.
9. After confirming the settings are valid, software can clear the `emac` bit in the `permodrst` register of the Reset Manager to bring the EMAC out of reset.

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

Note: These same steps can be applied to convert the HPS GMII to an RGMII, RMII or SGMII interface through the FPGA, except that in step 5 during FPGA configuration, you would load the appropriate soft adaptor for the interface and apply reset to it as well. The PHY interface select encoding would remain as 0x0. For the SGMII interface additional external transceiver logic would be required. Routing the Ethernet signals through the FPGA is useful for designs that are pin-limited in the HPS.

EMAC HPS Interface Initialization

To initialize the Ethernet controller to use the HPS interface, specific software steps must be followed including selecting the correct PHY interface through the System Manager.

In general, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate `emac` bit in the `permodrst` register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate `cnt` value in the `emac*clk` register in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. When all the clocks are valid, program the following clock settings:
 - a. Set the `physe1_*` field in the `ctrl` register of the System Manager (EMAC Group) to 0x1 to select the RGMII PHY interface.
 - b. Disable the Ethernet Controller FPGA interfaces by clearing the `emac_*` bit in the `module` register of the System Manager (FPGA Interface group).

5. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include AXI AxCache signal values, which are programmed in `l3_register` in the EMAC group of the System Manager.
6. Execute a register read back to confirm the clock and static configuration settings are valid.
7. After confirming the settings are valid, software can clear the `emac` bit in the `permodrst` register of the Reset Manager to bring the EMAC out of reset..

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

DMA Initialization

This section provides the instructions for initializing the DMA registers in the proper sequence. This initialization sequence can be done after the EMAC interface initialization has been completed. Perform the following steps to initialize the DMA:

1. Provide a software reset to reset all of the EMAC internal registers and logic. (DMA Register 0 (Bus Mode Register) – bit 0).[†]
2. Wait for the completion of the reset process (poll bit 0 of the DMA Register 0 (Bus Mode Register), which is only cleared after the reset operation is completed).[†]
3. Poll the bits of Register 11 (AHB or AXI Status) to confirm that all previously initiated (before software reset) or ongoing transactions are complete.

Note: If the application cannot poll the register after soft reset (because of performance reasons), then it is recommended that you continue with the next steps and check this register again (as mentioned in [12](#) on page 1-62) before triggering the DMA operations.[†]

4. Program the following fields to initialize the Bus Mode Register by setting values in DMA Register 0 (Bus Mode Register):[†]
 - Mixed Burst and AAL
 - Fixed burst or undefined burst[†]
 - Burst length values and burst mode values[†]
 - Descriptor Length (only valid if Ring Mode is used)[†]
 - TX and RX DMA Arbitration scheme[†]
5. Program the interface options in Register 10 (AXI Bus Mode Register). If fixed burst-length is enabled, then select the maximum burst-length possible on the bus (bits[7:1]).[†]
6. Create a proper descriptor chain for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (bit 31 of descriptor should be set). When OSF mode is used, at least two descriptors are required.
7. Make sure that your software creates three or more different transmit or receive descriptors in the chain before reusing any of the descriptors.[†]
8. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register) respectively).[†]
9. Program the following fields to initialize the mode of operation in Register 6 (Operation Mode Register):

- Receive and Transmit Store And Forward[†]
 - Receive and Transmit Threshold Control (RTC and TTC)[†]
 - Hardware Flow Control enable[†]
 - Flow Control Activation and De-activation thresholds for MTL Receive and Transmit FIFO buffers (RFA and RFD)[†]
 - Error frame and undersized good frame forwarding enable[†]
 - OSF Mode[†]
10. Clear the interrupt requests, by writing to those bits of the status register (interrupt bits only) that are set. For example, by writing 1 into bit 16, the normal interrupt summary clears this bit (DMA Register 5 (Status Register)).[†]
11. Enable the interrupts by programming Register 7 (Interrupt Enable Register).[†]
- Note:** Perform **12** on page 1-62 only if you did not perform **3** on page 1-61.[†]
12. Read Register 11 (AHB or AXI Status) to confirm that all previous transactions are complete.[†]
- Note:** If any previous transaction is still in progress when you read the Register 11 (AHB or AXI Status), then it is strongly recommended to check the slave components addressed by the master interface.[†]
13. Start the receive and transmit DMA by setting SR (bit 1) and ST (bit 13) of the control register (DMA Register 6 (Operation Mode Register)).[†]

Detailed bit map of the descriptor structure

EMAC Initialization and Configuration

The following EMAC configuration operations can be performed after DMA initialization. If the EMAC initialization and configuration is done before the DMA is set up, then enable the MAC receiver (last step below) only after the DMA is active. Otherwise, received frames fill the RX FIFO buffer and overflow.

1. Program the EMAC Register 4 (GMII Address Register) for controlling the management cycles for the external PHY. Bits[15:11] of the GMII Address Register are written with the Physical Layer Address of the PHY before reading or writing. Bit 0 indicates if the PHY is busy and is set before reading or writing to the PHY management interface. †
2. Read the 16-bit data of Register 5 (GMII Data Register) from the PHY for link up, speed of operation, and mode of operation, by specifying the appropriate address value in bits 15-11 of Register 4 (GMII Address Register). †
3. Provide the MAC address registers (Register 16 (MAC Address0 High Register) and Register 17 (MAC Address0 Low Register)). Because 128 MAC addresses are supported, you must program the MAC addresses accordingly.
4. Program Register 2 (Hash Table High Register) and Register 3 (Hash Table Low Register).
5. Program the following fields to set the appropriate filters for the incoming frames in Register 1 (MAC Frame Filter): †
 - Receive All †
 - Promiscuous mode †
 - Hash or Perfect Filter †
 - Unicast, multicast, broadcast, and control frames filter settings †
6. Program the following fields for proper flow control in Register 6 (Flow Control Register): †

- Pause time and other pause frame control bits †
 - Receive and Transmit Flow control bits †
 - Flow Control Busy/Backpressure Activate †
7. Program the Interrupt Mask register bits, as required and if applicable for your configuration. †
 8. Program the appropriate fields in Register 0 (MAC Configuration Register) to configure receive and transmit operation modes. After basic configuration is written, set bit 3 (TE) and bit 2 (RE) in this register to enable the receive and transmit state machines. †

Note: Do not change the configuration (such as duplex mode, speed, port, or loopback) when the EMAC DMA is actively transmitting or receiving. Software should change these parameters only when the EMAC DMA transmitter and receiver are not active.

Performing Normal Receive and Transmit Operation

For normal operation, perform the following steps: †

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive). †
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data. †
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and issuing a poll demand by writing 0 into the TX/RX poll demand registers, (Register 1 (Transmit Poll Demand Register) and Register 2 (Receive Poll Demand Register)). †
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (Register 18 (Current Host Transmit Descriptor Register) and Register 19 (Current Host Receive Descriptor Register)). †
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register 20 (Current Host Transmit Buffer Address Register) and Register 21 (Current Host Receive Buffer Address Register)). †

Stopping and Starting Transmission

Perform the following steps to pause the transmission for some time: †

1. Disable the transmit DMA (if applicable), by clearing bit 13 (Start or Stop Transmission Command) of Register 6 (Operation Mode Register). †
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Register 9 (Debug Register). †
3. Disable the EMAC transmitter and EMAC receiver by clearing Bit 3 (TE) and Bit 2 (RE) in Register 0 (MAC Configuration Register). †
4. Disable the receive DMA (if applicable), after making sure that the data in the RX FIFO buffer is transferred to the system memory (by reading Register 9 (Debug Register)). †
5. Make sure that both the TX FIFO buffer and RX FIFO buffer are empty. †
6. To re-start the operation, first start the DMA and then enable the EMAC transmitter and receiver. †

Programming Guidelines for Energy Efficient Ethernet

Entering and Exiting the TX LPI Mode

The Energy Efficient Ethernet (EEE) feature is available in the EMAC. To use it, perform the following steps during EMAC initialization:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values. †
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop the RX clock in LPI mode.) †
3. Program Bits[16:5], LST, and Bits[15:0], TWT, in Register 13 (LPI Timers Control Register). †
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 17 (PLS) of Register 12 (LPI Control and Status Register) accordingly. This update should be done whenever the link status in the PHY changes. †
5. Set Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to make the MAC enter the LPI state. The MAC enters the LPI mode after completing the transmission in progress and sets Bit 0 (TLPIEN). †

Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the TX FIFO buffer, you should set Bit 19 (LPITXA) in Register 12 (LPI Control and Status Register). †

Note: To switch off the transmit clock during the LPI state, use the `sbd_tx_clk_gating_ctrl_0` signal for gating the clock input. †

Note: To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of Register 12 (LPI Control and Status Register) to be generated. Restore the clocks before performing step 6 on page 1-64 when you want to come out of the LPI state. †

6. Clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI state. †

The MAC waits for the time programmed in Bits [15:0], TWT, before setting the TLPIEX interrupt status bit and resuming the transmission. †

Gating Off the CSR Clock in the LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode. †

Gating Off the CSR Clock in the RX LPI Mode

The following operations are performed when the MAC receives the LPI pattern from the PHY. †

1. The MAC RX enters the LPI mode and the RX LPI entry interrupt status [RLPIEN interrupt of Register 12 (LPI_Control_Status)] is set. †
2. The interrupt pin (`sbd_intr_o`) is asserted. The `sbd_intr_o` interrupt is cleared when the host reads the Register 12 (LPI_Control_Status). †

After the `sbd_intr_o` interrupt is asserted and the MAC TX is also in the LPI mode, you can gate off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR. †

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on `lpi_intr_o` (synchronous to `clk_rx_i`). The `lpi_intr_o` interrupt is cleared when Register 12 is read. †

Gating Off the CSR Clock in the TX LPI Mode

The following operations are performed when Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) is set: †

1. The Transmit LPI Entry interrupt (TLPIEN bit of Register 12) is set. †
2. The interrupt pin (`sbd_intr_o`) is asserted. The `sbd_intr_o` interrupt is cleared when the host reads the Register 12. †

After the `sbd_intr_o` interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR. †

To restore the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. †

After the CSR clock is resumed, clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI mode. †

Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output

Generating a Single Pulse on PPS

To generate single Pulse on PPS: †

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to 0001 to instruct the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers (register 455 and 456). †

Once the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse: †

1. Program the start time for the next pulse in the Target Time registers (register 455 and 456). This time should be more than the time at which the falling edge occurs for the previous pulse. †
2. Program the width of the next PPS signal output in Register 473 (PPS0 Width Register). †
3. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to generate a single pulse on the PPS signal output after the time at which the previous pulse is de-asserted. And at the time programmed in Target Time registers. If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the EMAC may generate only 1 extended pulse.

Generating a Pulse Train on PPS

To generate a pulse train on PPS: †

1. Program 11 or 10 (for an interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of the PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the interval value between the train of pulses on the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
5. Program Bits[3:0], PPSCMD, of Register 459 (PPS Control Register) to 0010 to instruct the MAC to generate a train of pulses on the PPS signal output with the start time programmed in the Target Time registers (register 455 and 456). By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. †
6. Program the stop value in the Target Time registers (register 455 and 456). Ensure that Bit 31 (TSTRBUSY) of Register 456 (Target Time Nanoseconds Register) is clear before programming the Target Time registers (register 455 and 456) again. †
7. Program the PPSCMD field (bit 3:0) of Register 459 (PPS Control Register) to 0100 to stop the train of pulses on the PPS signal output after the programmed stop time specified in step 6 on page 1-66 elapses. †

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in step 7 on page 1-66) by programming 0110 in the PPSCMD field before the time (programmed in step 6 on page 1-66) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in step 2 on page 1-66) elapses. †

Generating an Interrupt without Affecting the PPS

Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) enable you to program the Target Time registers (register 455 and 456) to do any one of the following: †

- Generate only interrupts. †
- Generate interrupts and the PPS start and stop time. †
- Generate only PPS start and stop time. †

To program the Target Time registers (register 455 and 456) to generate only interrupt events: †

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the target time interrupt. †
2. Program a target time value in the Target Time registers (register 455 and 456) to instruct the MAC to generate an interrupt when the target time elapses. If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

Ethernet MAC Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- EMAC Module 0
- EMAC Module 1

GMAC Register Group Register Descriptions

GMAC Register Group

Offset: 0x0

[MAC_Configuration](#) on page 17-132

The MAC Configuration register establishes receive and transmit operating modes.

MAC_Frame_Filter on page 17-139

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

GMII_Address on page 17-145

The GMII Address register controls the management cycles to the external PHY through the management interface.

GMII_Data on page 17-147

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

Flow_Control on page 17-148

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

VLAN_Tag on page 17-151

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

Version on page 17-153

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

Debug on page 17-153

The Debug register gives the status of all main blocks of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.

LPI_Control_Status on page 17-157

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

LPI_Timers_Control on page 17-160

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Interrupt_Status on page 17-161

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

Interrupt_Mask on page 17-164

The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register. The interrupt signal is `sbd_intr_o`.

MAC_Address0_High on page 17-165

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

MAC_Address0_Low on page 17-166

The MAC Address0 Low register holds the lower 32 bits of the first 6-byte MAC address of the station.

MAC_Address1_High on page 17-167

The MAC Address1 High register holds the upper 16 bits of the 2nd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address1_Low on page 17-170

The MAC Address1 Low register holds the lower 32 bits of the 2nd 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address2_High on page 17-171

The MAC Address2 High register holds the upper 16 bits of the 3rd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address2 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address2_Low on page 17-174

The MAC Address2 Low register holds the lower 32 bits of the 3rd 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address3_High on page 17-175

The MAC Address3 High register holds the upper 16 bits of the 4th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address3 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address3_Low on page 17-178

The MAC Address3 Low register holds the lower 32 bits of the 4th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address4_High on page 17-179

The MAC Address4 High register holds the upper 16 bits of the 5th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address4 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address4_Low on page 17-182

The MAC Address4 Low register holds the lower 32 bits of the 5th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address5_High on page 17-183

The MAC Address5 High register holds the upper 16 bits of the 6th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address5 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address5_Low on page 17-186

The MAC Address5 Low register holds the lower 32 bits of the 6th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address6_High on page 17-187

The MAC Address6 High register holds the upper 16 bits of the 7th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address6 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address6_Low on page 17-190

The MAC Address6 Low register holds the lower 32 bits of the 7th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address7_High on page 17-191

The MAC Address7 High register holds the upper 16 bits of the 8th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address7_Low on page 17-194

The MAC Address7 Low register holds the lower 32 bits of the 8th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address8_High on page 17-195

The MAC Address8 High register holds the upper 16 bits of the 9th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address8 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address8_Low on page 17-198

The MAC Address8 Low register holds the lower 32 bits of the 9th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address9_High on page 17-199

The MAC Address9 High register holds the upper 16 bits of the 10th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address9 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address9_Low on page 17-202

The MAC Address9 Low register holds the lower 32 bits of the 10th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address10_High on page 17-203

The MAC Address10 High register holds the upper 16 bits of the 11th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address10 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address10_Low on page 17-206

The MAC Address10 Low register holds the lower 32 bits of the 11th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address11_High on page 17-207

The MAC Address11 High register holds the upper 16 bits of the 12th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address11 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address11_Low on page 17-210

The MAC Address11 Low register holds the lower 32 bits of the 12th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address12_High on page 17-211

The MAC Address12 High register holds the upper 16 bits of the 13th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address12 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address12_Low on page 17-214

The MAC Address12 Low register holds the lower 32 bits of the 13th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address13_High on page 17-215

The MAC Address13 High register holds the upper 16 bits of the 14th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address13_Low on page 17-218

The MAC Address13 Low register holds the lower 32 bits of the 14th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address14_High on page 17-219

The MAC Address14 High register holds the upper 16 bits of the 15th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address14 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address14_Low on page 17-222

The MAC Address14 Low register holds the lower 32 bits of the 15th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address15_High on page 17-223

The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address15_Low on page 17-226

The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

SGMII_RGMII_SMII_Control_Status on page 17-227

The SGMII/RGMII/SMII Status register indicates the status signals received by the RGMII interface (selected at reset) from the PHY.

MMC_Control on page 17-228

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

MMC_Receive_Interrupt on page 17-230

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

MMC_Transmit_Interrupt on page 17-236

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

MMC_Receive_Interrupt_Mask on page 17-241

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when the receive statistic counters reach half of their maximum value, or maximum value. This register is 32-bits wide.

MMC_Transmit_Interrupt_Mask on page 17-247

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or maximum value. This register is 32-bits wide.

txoctetcount_gb on page 17-253

Number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad frames

txframecount_gb on page 17-254

Number of good and bad frames transmitted, exclusive of retried frames

txbroadcastframes_g on page 17-254

Number of good broadcast frames transmitted

txmulticastframes_g on page 17-255

Number of good multicast frames transmitted

tx64octets_gb on page 17-255

Number of good and bad frames transmitted with length 64 bytes, exclusive of preamble and retried frames

tx65to127octets_gb on page 17-256

Number of good and bad frames transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames

tx128to255octets_gb on page 17-257

Number of good and bad frames transmitted with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames

tx256to511octets_gb on page 17-257

Number of good and bad frames transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames

tx512to1023octets_gb on page 17-258

Number of good and bad frames transmitted with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames

tx1024tomaxoctets_gb on page 17-258

Number of good and bad frames transmitted with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames

txunicastframes_gb on page 17-259

Number of good and bad unicast frames transmitted

txmulticastframes_gb on page 17-260

Number of good and bad multicast frames transmitted

txbroadcastframes_gb on page 17-260

Number of good and bad broadcast frames transmitted

txunderflowerror on page 17-261

Number of frames aborted due to frame underflow error

txsinglecol_g on page 17-261

Number of successfully transmitted frames after a single collision in Half-duplex mode

txmulticol_g on page 17-262

Number of successfully transmitted frames after more than a single collision in Half-duplex mode

txdeferred on page 17-263

Number of successfully transmitted frames after a deferral in Halfduplex mode

txlatecol on page 17-263

Number of frames aborted due to late collision error

txexesscol on page 17-264

Number of frames aborted due to excessive (16) collision errors

txcarriererr on page 17-264

Number of frames aborted due to carrier sense error (no carrier or loss of carrier)

txoctetcnt on page 17-265

Number of bytes transmitted, exclusive of preamble, in good frames only

txframecount_g on page 17-265

Number of good frames transmitted

txexcessdef on page 17-266

Number of frames aborted due to excessive deferral error (deferred for more than two max-sized frame times)

txpauseframes on page 17-267

Number of good PAUSE frames transmitted

txvlanframes_g on page 17-267

Number of good VLAN frames transmitted, exclusive of retried frames

txoversize_g on page 17-268

Number of good and bad frames received

rxframecount_gb on page 17-268

Number of good and bad frames received

rxoctetcount_gb on page 17-269

Number of bytes received, exclusive of preamble, in good and bad frames

rxoctetcount_g on page 17-269

Number of bytes received, exclusive of preamble, only in good frames

rxbroadcastframes_g on page 17-270

Number of good broadcast frames received

rxmulticastframes_g on page 17-271

Number of good multicast frames received

rxrcrcerror on page 17-271

Number of frames received with CRC error

rxalignmenterror on page 17-272

Number of frames received with alignment (dribble) error. Valid only in 10/100 mode

rxrunterror on page 17-272

Number of frames received with runt (<64 bytes and CRC error) error

rxjabbererror on page 17-273

Number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames

rxundersize_g on page 17-274

Number of frames received with length less than 64 bytes, without any errors

rxoversize_g on page 17-274

Number of frames received with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames), without errors

rx64octets_gb on page 17-275

Number of good and bad frames received with length 64 bytes, exclusive of preamble

rx65to127octets_gb on page 17-275

Number of good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble

[rx128to255octets_gb](#) on page 17-276

Number of good and bad frames received with length between 128 and 255 (inclusive) bytes, exclusive of preamble

[rx256to511octets_gb](#) on page 17-277

Number of good and bad frames received with length between 256 and 511 (inclusive) bytes, exclusive of preamble

[rx512to1023octets_gb](#) on page 17-277

Number of good and bad frames received with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble

[rx1024tomaxoctets_gb](#) on page 17-278

Number of good and bad frames received with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames

[rxunicastframes_g](#) on page 17-278

Number of good unicast frames received

[rxlengtherror](#) on page 17-279

Number of frames received with length error (length type field not equal to frame size), for all frames with valid length field

[rxoutofrangetype](#) on page 17-280

Number of frames received with length field not equal to the valid frame size (greater than 1,500 but less than 1,536)

[rxpauseframes](#) on page 17-280

Number of good and valid PAUSE frames received

[rxfifooverflow](#) on page 17-281

Number of missed received frames due to FIFO overflow

[rxvlanframes_gb](#) on page 17-281

Number of good and bad VLAN frames received

[rxwatchdogerror](#) on page 17-282

Number of frames received with error due to watchdog timeout error (frames with a data load larger than 2,048 bytes)

[rxrcverror](#) on page 17-282

Number of frames received with Receive error or Frame Extension error on the GMII or MII interface.

[rxctrlframes_g](#) on page 17-283

Number of received good control frames.

[MMC_IPC_Receive_Interrupt_Mask](#) on page 17-284

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

MMC_IPC_Receive_Interrupt on page 17-290

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

rxipv4_gd_frms on page 17-296

Number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload

rxipv4_hdrerr_frms on page 17-297

Number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors

rxipv4_nopay_frms on page 17-297

Number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine

rxipv4_frag_frms on page 17-298

Number of good IPv4 datagrams with fragmentation

rxipv4_udtbl_frms on page 17-298

Number of good IPv4 datagrams received that had a UDP payload with checksum disabled

rxipv6_gd_frms on page 17-299

Number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads

rxipv6_hdrerr_frms on page 17-300

Number of IPv6 datagrams received with header errors (length or version mismatch)

rxipv6_nopay_frms on page 17-300

Number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers

rxudp_gd_frms on page 17-301

Number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented

rxudp_err_frms on page 17-301

Number of good IP datagrams whose UDP payload has a checksum error

rxtcp_gd_frms on page 17-302

Number of good IP datagrams with a good TCP payload

rxtcp_err_frms on page 17-302

Number of good IP datagrams whose TCP payload has a checksum error

rxicmp_gd_frms on page 17-303

Number of good IP datagrams with a good ICMP payload

rxicmp_err_frms on page 17-304

Number of good IP datagrams whose ICMP payload has a checksum error

rxipv4_gd_octets on page 17-304

Number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data

[rxipv4_hdrerr_octets](#) on page 17-305

Number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter

[rxipv4_nopay_octets](#) on page 17-305

Number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter

[rxipv4_frag_octets](#) on page 17-306

Number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter

[rxipv4_udtbl_octets](#) on page 17-307

Number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes

[rxipv6_gd_octets](#) on page 17-307

Number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data

[rxipv6_hdrerr_octets](#) on page 17-308

Number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the IPv6 headers Length field is used to update this counter

[rxipv6_nopay_octets](#) on page 17-308

Number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter

[rxudp_gd_octets](#) on page 17-309

Number of bytes received in a good UDP segment. This counter does not count IP header bytes

[rxudp_err_octets](#) on page 17-309

Number of bytes received in a UDP segment that had checksum errors

[rxtcp_gd_octets](#) on page 17-310

Number of bytes received in a good TCP segment

[rxtcperroctets](#) on page 17-311

Number of bytes received in a TCP segment with checksum errors

[rxicmp_gd_octets](#) on page 17-311

Number of bytes received in a good ICMP segment

[rxicmp_err_octets](#) on page 17-312

Number of bytes received in an ICMP segment with checksum errors

[L3_L4_Control0](#) on page 17-312

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

[Layer4_Address0](#) on page 17-315

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg0 on page 17-316

For IPv4 frames, the Layer 3 Address 0 Register 0 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg0 on page 17-317

For IPv4 frames, the Layer 3 Address 1 Register 0 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg0 on page 17-318

For IPv4 frames, the Layer 3 Address 2 Register 0 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg0 on page 17-319

For IPv4 frames, the Layer 3 Address 3 Register 0 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control1 on page 17-320

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address1 on page 17-323

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg1 on page 17-324

For IPv4 frames, the Layer 3 Address 0 Register 1 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg1 on page 17-324

For IPv4 frames, the Layer 3 Address 1 Register 1 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg1 on page 17-325

For IPv4 frames, the Layer 3 Address 2 Register 1 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg1 on page 17-326

For IPv4 frames, the Layer 3 Address 3 Register 1 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control2 on page 17-327

This register controls the operations of the filter 2 of Layer 3 and Layer 4.

Layer4_Address2 on page 17-329

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg2 on page 17-330

For IPv4 frames, the Layer 3 Address 0 Register 2 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg2 on page 17-331

For IPv4 frames, the Layer 3 Address 1 Register 2 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg2 on page 17-332

For IPv4 frames, the Layer 3 Address 2 Register 2 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg2 on page 17-333

For IPv4 frames, the Layer 3 Address 3 Register 2 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control3 on page 17-334

This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address3 on page 17-337

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg3 on page 17-338

For IPv4 frames, the Layer 3 Address 0 Register 3 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg3 on page 17-338

For IPv4 frames, the Layer 3 Address 1 Register 3 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg3 on page 17-339

For IPv4 frames, the Layer 3 Address 2 Register 3 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg3 on page 17-340

For IPv4 frames, the Layer 3 Address 3 Register 3 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

Hash_Table_Reg0 on page 17-341

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Hash_Table_Reg1 on page 17-342

This register contains the second 32 bits of the hash table.

Hash_Table_Reg2 on page 17-342

This register contains the third 32 bits of the hash table.

Hash_Table_Reg3 on page 17-343

This register contains the fourth 32 bits of the hash table.

Hash_Table_Reg4 on page 17-343

This register contains the fifth 32 bits of the hash table.

Hash_Table_Reg5 on page 17-344

This register contains the sixth 32 bits of the hash table.

Hash_Table_Reg6 on page 17-345

This register contains the seventh 32 bits of the hash table.

Hash_Table_Reg7 on page 17-345

This register contains the eighth 32 bits of the hash table.

VLAN_Hash_Table_Reg on page 17-346

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Timestamp_Control on page 17-346

This register controls the operation of the System Time generator and the processing of PTP packets for timestamping in the Receiver.

Sub_Second_Increment on page 17-351

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of `clk_ptp_ref_i`. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

System_Time_Seconds on page 17-352

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from `clk_ptp_ref_i` to `l3_sp_clk`).

System_Time_Nanoseconds on page 17-353

The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When TCTRLSSR is set, each bit represents 1 ns and the maximum value is 0x3B9A_C9FF, after which it rolls-over to zero.

System_Time_Seconds_Update on page 17-353

The System Time - Seconds Update register, along with the System Time - Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both of these registers before setting the TSINIT or TSUPDT bits in the Timestamp Control register.

System_Time_Nanoseconds_Update on page 17-354

Update system time

Timestamp_Addend on page 17-355

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in Register 448). This register content is added to a 32-bit accumulator in every clock cycle (of `clk_ptp_ref_i`) and the system time is updated whenever the accumulator overflows.

Target_Time_Seconds on page 17-356

The Target Time Seconds register, along with Target Time Nanoseconds register, is used to schedule an interrupt event (Register 458[1] when Advanced Timestamping is enabled; otherwise, TS interrupt bit in Register14[9]) when the system time exceeds the value programmed in these registers.

Target_Time_Nanoseconds on page 17-356

Target time

System_Time_Higher_Word_Seconds on page 17-357

System time higher word

Timestamp_Status on page 17-358

Timestamp status. All bits except Bits[27:25] get cleared when the host reads this register.

PPS_Control on page 17-360

Controls timestamp Pulse-Per-Second output

Auxiliary_Timestamp_Nanoseconds on page 17-363

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

Auxiliary_Timestamp_Seconds on page 17-363

Contains the higher 32 bits (Seconds field) of the auxiliary timestamp.

PPS0_Interval on page 17-364

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (`ptp_pps_o[0]`).

PPS0_Width on page 17-365

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (`ptp_pps_o[0]`).

MAC_Address16_High on page 17-366

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address16_Low on page 17-369

The MAC Address16 Low register holds the lower 32 bits of the 17th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address17_High on page 17-370

The MAC Address17 High register holds the upper 16 bits of the 18th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address17 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address17_Low on page 17-373

The MAC Address17 Low register holds the lower 32 bits of the 18th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address18_High on page 17-374

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address18_Low on page 17-377

The MAC Address18 Low register holds the lower 32 bits of the 19th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address19_High on page 17-378

The MAC Address19 High register holds the upper 16 bits of the 20th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address19 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address19_Low on page 17-381

The MAC Address19 Low register holds the lower 32 bits of the 20th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address20_High on page 17-382

The MAC Address20 High register holds the upper 16 bits of the 21th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address20 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address20_Low on page 17-385

The MAC Address20 Low register holds the lower 32 bits of the 21th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address21_High on page 17-386

The MAC Address21 High register holds the upper 16 bits of the 22th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address21 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address21_Low on page 17-389

The MAC Address21 Low register holds the lower 32 bits of the 22th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address22_High on page 17-390

The MAC Address22 High register holds the upper 16 bits of the 23th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address22 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address22_Low on page 17-393

The MAC Address22 Low register holds the lower 32 bits of the 23th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address23_High on page 17-394

The MAC Address23 High register holds the upper 16 bits of the 24th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address23 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address23_Low on page 17-397

The MAC Address23 Low register holds the lower 32 bits of the 24th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address24_High on page 17-398

The MAC Address24 High register holds the upper 16 bits of the 25th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address24 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address24_Low on page 17-401

The MAC Address24 Low register holds the lower 32 bits of the 25th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address25_High on page 17-402

The MAC Address25 High register holds the upper 16 bits of the 26th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address25 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address25_Low on page 17-405

The MAC Address25 Low register holds the lower 32 bits of the 26th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address26_High on page 17-406

The MAC Address26 High register holds the upper 16 bits of the 27th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address26_Low on page 17-409

The MAC Address26 Low register holds the lower 32 bits of the 27th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address27_High on page 17-410

The MAC Address27 High register holds the upper 16 bits of the 28th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address27 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address27_Low on page 17-413

The MAC Address27 Low register holds the lower 32 bits of the 28th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address28_High on page 17-414

The MAC Address28 High register holds the upper 16 bits of the 29th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address28 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address28_Low on page 17-417

The MAC Address28 Low register holds the lower 32 bits of the 29th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address29_High on page 17-418

The MAC Address29 High register holds the upper 16 bits of the 30th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address29 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address29_Low on page 17-421

The MAC Address29 Low register holds the lower 32 bits of the 30th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address30_High on page 17-422

The MAC Address30 High register holds the upper 16 bits of the 31th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address30 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address30_Low on page 17-425

The MAC Address30 Low register holds the lower 32 bits of the 31th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address31_High on page 17-426

The MAC Address31 High register holds the upper 16 bits of the 32th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address31 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address31_Low on page 17-429

The MAC Address31 Low register holds the lower 32 bits of the 32th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address32_High on page 17-430

The MAC Address32 High register holds the upper 16 bits of the 33th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address32 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address32_Low on page 17-433

The MAC Address32 Low register holds the lower 32 bits of the 33th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address33_High on page 17-434

The MAC Address33 High register holds the upper 16 bits of the 34th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address33 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address33_Low on page 17-437

The MAC Address33 Low register holds the lower 32 bits of the 34th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address34_High on page 17-438

The MAC Address34 High register holds the upper 16 bits of the 35th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address34 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address34_Low on page 17-441

The MAC Address34 Low register holds the lower 32 bits of the 35th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address35_High on page 17-442

The MAC Address35 High register holds the upper 16 bits of the 36th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address35 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address35_Low on page 17-445

The MAC Address35 Low register holds the lower 32 bits of the 36th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address36_High on page 17-446

The MAC Address36 High register holds the upper 16 bits of the 37th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address36 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address36_Low on page 17-449

The MAC Address36 Low register holds the lower 32 bits of the 37th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address37_High on page 17-450

The MAC Address37 High register holds the upper 16 bits of the 38th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address37 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address37_Low on page 17-453

The MAC Address37 Low register holds the lower 32 bits of the 38th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address38_High on page 17-454

The MAC Address38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address38 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address38_Low on page 17-457

The MAC Address38 Low register holds the lower 32 bits of the 39th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address39_High on page 17-458

The MAC Address39 High register holds the upper 16 bits of the 40th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address39 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address39_Low on page 17-461

The MAC Address39 Low register holds the lower 32 bits of the 40th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address40_High on page 17-462

The MAC Address40 High register holds the upper 16 bits of the 41th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address40 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address40_Low on page 17-465

The MAC Address40 Low register holds the lower 32 bits of the 41th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address41_High on page 17-466

The MAC Address41 High register holds the upper 16 bits of the 42th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address41 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address41_Low on page 17-469

The MAC Address41 Low register holds the lower 32 bits of the 42th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address42_High on page 17-470

The MAC Address42 High register holds the upper 16 bits of the 43th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address42 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address42_Low on page 17-473

The MAC Address42 Low register holds the lower 32 bits of the 43th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address43_High on page 17-474

The MAC Address43 High register holds the upper 16 bits of the 44th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address43 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address43_Low on page 17-477

The MAC Address43 Low register holds the lower 32 bits of the 44th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address44_High on page 17-478

The MAC Address44 High register holds the upper 16 bits of the 45th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address44 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address44_Low on page 17-481

The MAC Address44 Low register holds the lower 32 bits of the 45th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address45_High on page 17-482

The MAC Address45 High register holds the upper 16 bits of the 46th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address45 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address45_Low on page 17-485

The MAC Address45 Low register holds the lower 32 bits of the 46th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address46_High on page 17-486

The MAC Address46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address46 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address46_Low on page 17-489

The MAC Address46 Low register holds the lower 32 bits of the 47th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address47_High on page 17-490

The MAC Address47 High register holds the upper 16 bits of the 48th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address47 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address47_Low on page 17-493

The MAC Address47 Low register holds the lower 32 bits of the 48th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address48_High on page 17-494

The MAC Address48 High register holds the upper 16 bits of the 49th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address48 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address48_Low on page 17-497

The MAC Address48 Low register holds the lower 32 bits of the 49th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address49_High on page 17-498

The MAC Address49 High register holds the upper 16 bits of the 50th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address49 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address49_Low on page 17-501

The MAC Address49 Low register holds the lower 32 bits of the 50th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address50_High on page 17-502

The MAC Address50 High register holds the upper 16 bits of the 51th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address50 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address50_Low on page 17-505

The MAC Address50 Low register holds the lower 32 bits of the 51th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address51_High on page 17-506

The MAC Address51 High register holds the upper 16 bits of the 52th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address51 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address51_Low on page 17-509

The MAC Address51 Low register holds the lower 32 bits of the 52th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address52_High on page 17-510

The MAC Address52 High register holds the upper 16 bits of the 53th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address52 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address52_Low on page 17-513

The MAC Address52 Low register holds the lower 32 bits of the 53th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address53_High on page 17-514

The MAC Address53 High register holds the upper 16 bits of the 54th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address53 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address53_Low on page 17-517

The MAC Address53 Low register holds the lower 32 bits of the 54th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address54_High on page 17-518

The MAC Address54 High register holds the upper 16 bits of the 55th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address54 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address54_Low on page 17-521

The MAC Address54 Low register holds the lower 32 bits of the 55th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address55_High on page 17-522

The MAC Address55 High register holds the upper 16 bits of the 56th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address55 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address55_Low on page 17-525

The MAC Address55 Low register holds the lower 32 bits of the 56th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address56_High on page 17-526

The MAC Address56 High register holds the upper 16 bits of the 57th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address56 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address56_Low on page 17-529

The MAC Address56 Low register holds the lower 32 bits of the 57th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address57_High on page 17-530

The MAC Address57 High register holds the upper 16 bits of the 58th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address57 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address57_Low on page 17-533

The MAC Address57 Low register holds the lower 32 bits of the 58th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address58_High on page 17-534

The MAC Address58 High register holds the upper 16 bits of the 59th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address58 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address58_Low on page 17-537

The MAC Address58 Low register holds the lower 32 bits of the 59th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address59_High on page 17-538

The MAC Address59 High register holds the upper 16 bits of the 60th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address59 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address59_Low on page 17-541

The MAC Address59 Low register holds the lower 32 bits of the 60th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address60_High on page 17-542

The MAC Address60 High register holds the upper 16 bits of the 61th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address60 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address60_Low on page 17-545

The MAC Address60 Low register holds the lower 32 bits of the 61th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address61_High on page 17-546

The MAC Address61 High register holds the upper 16 bits of the 62th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address61 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address61_Low on page 17-549

The MAC Address61 Low register holds the lower 32 bits of the 62th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address62_High on page 17-550

The MAC Address62 High register holds the upper 16 bits of the 63th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address62_Low on page 17-553

The MAC Address62 Low register holds the lower 32 bits of the 63th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address63_High on page 17-554

The MAC Address63 High register holds the upper 16 bits of the 64th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address63 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address63_Low on page 17-557

The MAC Address63 Low register holds the lower 32 bits of the 64th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address64_High on page 17-558

The MAC Address64 High register holds the upper 16 bits of the 65th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address64 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address64_Low on page 17-561

The MAC Address64 Low register holds the lower 32 bits of the 65th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address65_High on page 17-562

The MAC Address65 High register holds the upper 16 bits of the 66th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address65 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address65_Low on page 17-565

The MAC Address65 Low register holds the lower 32 bits of the 66th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address66_High on page 17-566

The MAC Address66 High register holds the upper 16 bits of the 67th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address66 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address66_Low on page 17-569

The MAC Address66 Low register holds the lower 32 bits of the 67th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address67_High on page 17-570

The MAC Address67 High register holds the upper 16 bits of the 68th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address67 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address67_Low on page 17-573

The MAC Address67 Low register holds the lower 32 bits of the 68th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address68_High on page 17-574

The MAC Address68 High register holds the upper 16 bits of the 69th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address68 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address68_Low on page 17-577

The MAC Address68 Low register holds the lower 32 bits of the 69th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address69_High on page 17-578

The MAC Address69 High register holds the upper 16 bits of the 70th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address69 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address69_Low on page 17-581

The MAC Address69 Low register holds the lower 32 bits of the 70th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address70_High on page 17-582

The MAC Address70 High register holds the upper 16 bits of the 71th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address70 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address70_Low on page 17-585

The MAC Address70 Low register holds the lower 32 bits of the 71th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address71_High on page 17-586

The MAC Address71 High register holds the upper 16 bits of the 72th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address71 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address71_Low on page 17-589

The MAC Address71 Low register holds the lower 32 bits of the 72th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address72_High on page 17-590

The MAC Address72 High register holds the upper 16 bits of the 73th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address72 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address72_Low on page 17-593

The MAC Address72 Low register holds the lower 32 bits of the 73th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address73_High on page 17-594

The MAC Address73 High register holds the upper 16 bits of the 74th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address73 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address73_Low on page 17-597

The MAC Address73 Low register holds the lower 32 bits of the 74th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address74_High on page 17-598

The MAC Address74 High register holds the upper 16 bits of the 75th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address74 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address74_Low on page 17-601

The MAC Address74 Low register holds the lower 32 bits of the 75th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address75_High on page 17-602

The MAC Address75 High register holds the upper 16 bits of the 76th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address75 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address75_Low on page 17-605

The MAC Address75 Low register holds the lower 32 bits of the 76th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address76_High on page 17-606

The MAC Address76 High register holds the upper 16 bits of the 77th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address76 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address76_Low on page 17-609

The MAC Address76 Low register holds the lower 32 bits of the 77th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address77_High on page 17-610

The MAC Address77 High register holds the upper 16 bits of the 78th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address77 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address77_Low on page 17-613

The MAC Address77 Low register holds the lower 32 bits of the 78th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address78_High on page 17-614

The MAC Address78 High register holds the upper 16 bits of the 79th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address78 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address78_Low on page 17-617

The MAC Address78 Low register holds the lower 32 bits of the 79th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address79_High on page 17-618

The MAC Address79 High register holds the upper 16 bits of the 80th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address79 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address79_Low on page 17-621

The MAC Address79 Low register holds the lower 32 bits of the 80th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address80_High on page 17-622

The MAC Address80 High register holds the upper 16 bits of the 81th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address80 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address80_Low on page 17-625

The MAC Address80 Low register holds the lower 32 bits of the 81th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address81_High on page 17-626

The MAC Address81 High register holds the upper 16 bits of the 82th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address81 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address81_Low on page 17-629

The MAC Address81 Low register holds the lower 32 bits of the 82th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address82_High on page 17-630

The MAC Address82 High register holds the upper 16 bits of the 83th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address82 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address82_Low on page 17-633

The MAC Address82 Low register holds the lower 32 bits of the 83th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address83_High on page 17-634

The MAC Address83 High register holds the upper 16 bits of the 84th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address83 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address83_Low on page 17-637

The MAC Address83 Low register holds the lower 32 bits of the 84th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address84_High on page 17-638

The MAC Address84 High register holds the upper 16 bits of the 85th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address84 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address84_Low on page 17-641

The MAC Address84 Low register holds the lower 32 bits of the 85th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address85_High on page 17-642

The MAC Address85 High register holds the upper 16 bits of the 86th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address85 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address85_Low on page 17-645

The MAC Address85 Low register holds the lower 32 bits of the 86th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address86_High on page 17-646

The MAC Address86 High register holds the upper 16 bits of the 87th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address86 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address86_Low on page 17-649

The MAC Address86 Low register holds the lower 32 bits of the 87th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address87_High on page 17-650

The MAC Address87 High register holds the upper 16 bits of the 88th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address87 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address87_Low on page 17-653

The MAC Address87 Low register holds the lower 32 bits of the 88th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address88_High on page 17-654

The MAC Address88 High register holds the upper 16 bits of the 89th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address88 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address88_Low on page 17-657

The MAC Address88 Low register holds the lower 32 bits of the 89th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address89_High on page 17-658

The MAC Address89 High register holds the upper 16 bits of the 90th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address89 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address89_Low on page 17-661

The MAC Address89 Low register holds the lower 32 bits of the 90th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address90_High on page 17-662

The MAC Address90 High register holds the upper 16 bits of the 91th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address90 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address90_Low on page 17-665

The MAC Address90 Low register holds the lower 32 bits of the 91th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address91_High on page 17-666

The MAC Address91 High register holds the upper 16 bits of the 92th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address91 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address91_Low on page 17-669

The MAC Address91 Low register holds the lower 32 bits of the 92th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address92_High on page 17-670

The MAC Address92 High register holds the upper 16 bits of the 93th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address92 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address92_Low on page 17-673

The MAC Address92 Low register holds the lower 32 bits of the 93th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address93_High on page 17-674

The MAC Address93 High register holds the upper 16 bits of the 94th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address93 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address93_Low on page 17-677

The MAC Address93 Low register holds the lower 32 bits of the 94th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address94_High on page 17-678

The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address94_Low on page 17-681

The MAC Address94 Low register holds the lower 32 bits of the 95th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address95_High on page 17-682

The MAC Address95 High register holds the upper 16 bits of the 96th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address95 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address95_Low on page 17-685

The MAC Address95 Low register holds the lower 32 bits of the 96th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address96_High on page 17-686

The MAC Address96 High register holds the upper 16 bits of the 97th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address96 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address96_Low on page 17-689

The MAC Address96 Low register holds the lower 32 bits of the 97th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address97_High on page 17-690

The MAC Address97 High register holds the upper 16 bits of the 98th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address97 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address97_Low on page 17-693

The MAC Address97 Low register holds the lower 32 bits of the 98th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address98_High on page 17-694

The MAC Address98 High register holds the upper 16 bits of the 99th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address98 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address98_Low on page 17-697

The MAC Address98 Low register holds the lower 32 bits of the 99th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address99_High on page 17-698

The MAC Address99 High register holds the upper 16 bits of the 100th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address99 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address99_Low on page 17-701

The MAC Address99 Low register holds the lower 32 bits of the 100th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address100_High on page 17-702

The MAC Address100 High register holds the upper 16 bits of the 101th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address100 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address100_Low on page 17-705

The MAC Address100 Low register holds the lower 32 bits of the 101th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address101_High on page 17-706

The MAC Address101 High register holds the upper 16 bits of the 102th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address101 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address101_Low on page 17-709

The MAC Address101 Low register holds the lower 32 bits of the 102th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address102_High on page 17-710

The MAC Address102 High register holds the upper 16 bits of the 103th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address102 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address102_Low on page 17-713

The MAC Address102 Low register holds the lower 32 bits of the 103th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address103_High on page 17-714

The MAC Address103 High register holds the upper 16 bits of the 104th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address103 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address103_Low on page 17-717

The MAC Address103 Low register holds the lower 32 bits of the 104th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address104_High on page 17-718

The MAC Address104 High register holds the upper 16 bits of the 105th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address104 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address104_Low on page 17-721

The MAC Address104 Low register holds the lower 32 bits of the 105th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address105_High on page 17-722

The MAC Address105 High register holds the upper 16 bits of the 106th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address105 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address105_Low on page 17-725

The MAC Address105 Low register holds the lower 32 bits of the 106th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address106_High on page 17-726

The MAC Address106 High register holds the upper 16 bits of the 107th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address106 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address106_Low on page 17-729

The MAC Address106 Low register holds the lower 32 bits of the 107th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address107_High on page 17-730

The MAC Address107 High register holds the upper 16 bits of the 108th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address107 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address107_Low on page 17-733

The MAC Address107 Low register holds the lower 32 bits of the 108th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address108_High on page 17-734

The MAC Address108 High register holds the upper 16 bits of the 109th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address108 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address108_Low on page 17-737

The MAC Address108 Low register holds the lower 32 bits of the 109th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address109_High on page 17-738

The MAC Address109 High register holds the upper 16 bits of the 110th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address109 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address109_Low on page 17-741

The MAC Address109 Low register holds the lower 32 bits of the 110th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address110_High on page 17-742

The MAC Address110 High register holds the upper 16 bits of the 111th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address110 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address110_Low on page 17-745

The MAC Address110 Low register holds the lower 32 bits of the 111th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address111_High on page 17-746

The MAC Address111 High register holds the upper 16 bits of the 112th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address111 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address111_Low on page 17-749

The MAC Address111 Low register holds the lower 32 bits of the 112th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address112_High on page 17-750

The MAC Address112 High register holds the upper 16 bits of the 113th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address112 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address112_Low on page 17-753

The MAC Address112 Low register holds the lower 32 bits of the 113th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address113_High on page 17-754

The MAC Address113 High register holds the upper 16 bits of the 114th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address113 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address113_Low on page 17-757

The MAC Address113 Low register holds the lower 32 bits of the 114th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address114_High on page 17-758

The MAC Address114 High register holds the upper 16 bits of the 115th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address114 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address114_Low on page 17-761

The MAC Address114 Low register holds the lower 32 bits of the 115th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address115_High on page 17-762

The MAC Address115 High register holds the upper 16 bits of the 116th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address115 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address115_Low on page 17-765

The MAC Address115 Low register holds the lower 32 bits of the 116th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address116_High on page 17-766

The MAC Address116 High register holds the upper 16 bits of the 117th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address116 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address116_Low on page 17-769

The MAC Address116 Low register holds the lower 32 bits of the 117th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address117_High on page 17-770

The MAC Address117 High register holds the upper 16 bits of the 118th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address117 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address117_Low on page 17-773

The MAC Address117 Low register holds the lower 32 bits of the 118th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address118_High on page 17-774

The MAC Address118 High register holds the upper 16 bits of the 119th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address118 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address118_Low on page 17-777

The MAC Address118 Low register holds the lower 32 bits of the 119th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address119_High on page 17-778

The MAC Address119 High register holds the upper 16 bits of the 120th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address119 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address119_Low on page 17-781

The MAC Address119 Low register holds the lower 32 bits of the 120th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address120_High on page 17-782

The MAC Address120 High register holds the upper 16 bits of the 121th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address120 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address120_Low on page 17-785

The MAC Address120 Low register holds the lower 32 bits of the 121th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address121_High on page 17-786

The MAC Address121 High register holds the upper 16 bits of the 122th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address121 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address121_Low on page 17-789

The MAC Address121 Low register holds the lower 32 bits of the 122th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address122_High on page 17-790

The MAC Address122 High register holds the upper 16 bits of the 123th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address122 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address122_Low on page 17-793

The MAC Address122 Low register holds the lower 32 bits of the 123th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address123_High on page 17-794

The MAC Address123 High register holds the upper 16 bits of the 124th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address123 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address123_Low on page 17-797

The MAC Address123 Low register holds the lower 32 bits of the 124th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address124_High on page 17-798

The MAC Address124 High register holds the upper 16 bits of the 125th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address124 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address124_Low on page 17-801

The MAC Address124 Low register holds the lower 32 bits of the 125th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address125_High on page 17-802

The MAC Address125 High register holds the upper 16 bits of the 126th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address125 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address125_Low on page 17-805

The MAC Address125 Low register holds the lower 32 bits of the 126th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address126_High on page 17-806

The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address126 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address126_Low on page 17-809

The MAC Address126 Low register holds the lower 32 bits of the 127th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address127_High on page 17-810

The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address127 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address127_Low on page 17-813

The MAC Address127 Low register holds the lower 32 bits of the 128th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Configuration

The MAC Configuration register establishes receive and transmit operating modes.

Module Instance	Base Address	Register Address

MAC_Configuration Fields

Bit	Name	Description	Access	Reset						
27	twokpe	When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status.	RW	0x0						
25	cst	When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Strip Ether Frames Off</td> </tr> <tr> <td>0x1</td> <td>Strip Ether Frames On</td> </tr> </tbody> </table>	Value	Description	0x0	Strip Ether Frames Off	0x1	Strip Ether Frames On	RW	0x0

Bit	Name	Description	Access	Reset						
4	dc	<p>When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on GMII or MII. Defer time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Deferral Check Enabled</td> </tr> <tr> <td>0x0</td> <td>Deferral Check Disabled</td> </tr> </tbody> </table>	Value	Description	0x1	Deferral Check Enabled	0x0	Deferral Check Disabled	RW	0x0

MAC_Frame_Filter

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

Bit	Name	Description	Access	Reset																														
5:2	cr	<p>The CSR Clock Range selection determines the frequency of the MDC clock according to the l3_sp_clk frequency used in your design. The suggested range of l3_sp_clk frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when l3_sp_clk is of 100 MHz frequency and you program these bits as 1010, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Only use the values larger than 7 if the interfacing chips support faster MDC clocks.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>l3_sp_clk 60-100Mhz and MDC clock = l3_sp_clk/42</td> </tr> <tr> <td>0x1</td> <td>l3_sp_clk 100-150Mhz and MDC clock = l3_sp_clk/62</td> </tr> <tr> <td>0x2</td> <td>l3_sp_clk 25-35Mhz and MDC clock = l3_sp_clk/16</td> </tr> <tr> <td>0x3</td> <td>l3_sp_clk 35-60Mhz and MDC clock = l3_sp_clk/26</td> </tr> <tr> <td>0x4</td> <td>l3_sp_clk 150-250Mhz and MDC clock = l3_sp_clk/102</td> </tr> <tr> <td>0x5</td> <td>l3_sp_clk 250-300Mhz and MDC clock = l3_sp_clk/124</td> </tr> <tr> <td>0x8</td> <td>l3_sp_clk/4</td> </tr> <tr> <td>0x9</td> <td>l3_sp_clk/6</td> </tr> <tr> <td>0xa</td> <td>l3_sp_clk/8</td> </tr> <tr> <td>0xb</td> <td>l3_sp_clk/10</td> </tr> <tr> <td>0xc</td> <td>l3_sp_clk/12</td> </tr> <tr> <td>0xd</td> <td>l3_sp_clk/14</td> </tr> <tr> <td>0xe</td> <td>l3_sp_clk/16</td> </tr> <tr> <td>0xf</td> <td>l3_sp_clk/18</td> </tr> </tbody> </table>	Value	Description	0x0	l3_sp_clk 60-100Mhz and MDC clock = l3_sp_clk/42	0x1	l3_sp_clk 100-150Mhz and MDC clock = l3_sp_clk/62	0x2	l3_sp_clk 25-35Mhz and MDC clock = l3_sp_clk/16	0x3	l3_sp_clk 35-60Mhz and MDC clock = l3_sp_clk/26	0x4	l3_sp_clk 150-250Mhz and MDC clock = l3_sp_clk/102	0x5	l3_sp_clk 250-300Mhz and MDC clock = l3_sp_clk/124	0x8	l3_sp_clk/4	0x9	l3_sp_clk/6	0xa	l3_sp_clk/8	0xb	l3_sp_clk/10	0xc	l3_sp_clk/12	0xd	l3_sp_clk/14	0xe	l3_sp_clk/16	0xf	l3_sp_clk/18	RW	0x0

Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

2	rfe	<p>When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Decode Func. of Pause Frame Disabled</td> </tr> <tr> <td>0x1</td> <td>MAC decodes the received Pause</td> </tr> </tbody> </table>	Value	Description	0x0	Decode Func. of Pause Frame Disabled	0x1	MAC decodes the received Pause	RW	0x0
Value	Description									
0x0	Decode Func. of Pause Frame Disabled									
0x1	MAC decodes the received Pause									
1	tfe	<p>In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transmit Flow Control Disable</td> </tr> <tr> <td>0x1</td> <td>Transmit Flow Control Enable</td> </tr> </tbody> </table>	Value	Description	0x0	Transmit Flow Control Disable	0x1	Transmit Flow Control Enable	RW	0x0
Value	Description									
0x0	Transmit Flow Control Disable									
0x1	Transmit Flow Control Enable									

Bit	Name	Description	Access	Reset						
0	fca_bpa	<p>This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Pause Ctrl Frame and BPA off</td> </tr> <tr> <td>0x1</td> <td>Init Pause Ctrl Frame and BPA</td> </tr> </tbody> </table>	Value	Description	0x0	Pause Ctrl Frame and BPA off	0x1	Init Pause Ctrl Frame and BPA	RW	0x0
Value	Description									
0x0	Pause Ctrl Frame and BPA off									
0x1	Init Pause Ctrl Frame and BPA									

VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

VLAN_Tag Fields

Bit	Name	Description	Access	Reset						
19	vthm	When set, the most significant four bits of the VLAN tag's CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed.	RW	0x0						
18	esvl	When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.	RW	0x0						
17	vtim	When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.	RW	0x0						
16	etv	When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Disable 12-Bit VLAN Tag Compare</td> </tr> <tr> <td>0x1</td> <td>Enable 12-Bit VLAN Tag Compare</td> </tr> </tbody> </table>	Value	Description	0x0	Disable 12-Bit VLAN Tag Compare	0x1	Enable 12-Bit VLAN Tag Compare	RW	0x0
Value	Description									
0x0	Disable 12-Bit VLAN Tag Compare									
0x1	Enable 12-Bit VLAN Tag Compare									

Bit	Name	Description	Access	Reset
15:0	v1	This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.	RW	0x0

Version

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

LPI_Control_Status Fields

Bit	Name	Description	Access	Reset						
19	lpitxa	<p>This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the transmit side. This bit is not functional in the GMAC-CORE configuration in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding frames (in the core) and pending frames (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any frame for transmission or the application issues a TX FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If TX FIFO Flush is set, in Bit 20 of Register 6 (Operation Mode Register), when the MAC is in the LPI mode, the MAC exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>LPI TX Automate Disabled</td> </tr> <tr> <td>0x1</td> <td>LPI TX Automate Enabled</td> </tr> </tbody> </table>	Value	Description	0x0	LPI TX Automate Disabled	0x1	LPI TX Automate Enabled	RW	0x0

LPI_Timers_Control Fields

Bit	Name	Description	Access	Reset
25:16	1st	This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.	RW	0x3E8
15:0	twt	This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.	RW	0x0

Interrupt_Status

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

MAC_Address6_High

The MAC Address6 High register holds the upper 16 bits of the 7th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address6 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 8th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address8_High

The MAC Address8 High register holds the upper 16 bits of the 9th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address8 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address14_High

The MAC Address14 High register holds the upper 16 bits of the 15th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address14 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Bit	Name	Description	Access	Reset						
0	lnkmod	This bit indicates the current mode of operation of the link <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Half Duplex</td> </tr> <tr> <td>0x1</td> <td>Full Duplex</td> </tr> </tbody> </table>	Value	Description	0x0	Half Duplex	0x1	Full Duplex	RO	0x0
Value	Description									
0x0	Half Duplex									
0x1	Full Duplex									

MMC_Control

The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

MMC_Control Fields

Bit	Name	Description	Access	Reset
8	ucdbc	When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.	RW	0x0

Bit	Name	Description	Access	Reset						
5	cntprstlvl	<p>When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Preset All Counters to almost-half</td> </tr> <tr> <td>0x1</td> <td>Present All Counters almost-full</td> </tr> </tbody> </table>	Value	Description	0x0	Preset All Counters to almost-half	0x1	Present All Counters almost-full	RW	0x0
Value	Description									
0x0	Preset All Counters to almost-half									
0x1	Present All Counters almost-full									
4	cntprst	<p>When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Counters not preset</td> </tr> <tr> <td>0x1</td> <td>Counters preset to full or almost full</td> </tr> </tbody> </table>	Value	Description	0x0	Counters not preset	0x1	Counters preset to full or almost full	RW	0x0
Value	Description									
0x0	Counters not preset									
0x1	Counters preset to full or almost full									
3	cntfreez	<p>When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Update MMC Counters</td> </tr> <tr> <td>0x1</td> <td>Freeze MMC counters to current value</td> </tr> </tbody> </table>	Value	Description	0x0	Update MMC Counters	0x1	Freeze MMC counters to current value	RW	0x0
Value	Description									
0x0	Update MMC Counters									
0x1	Freeze MMC counters to current value									

Bit	Name	Description	Access	Reset						
2	rstonrd	<p>When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No reset after read</td> </tr> <tr> <td>0x1</td> <td>Reset after read</td> </tr> </tbody> </table>	Value	Description	0x0	No reset after read	0x1	Reset after read	RW	0x0
Value	Description									
0x0	No reset after read									
0x1	Reset after read									
1	cntstopro	<p>When this bit is set, after reaching maximum value, the counter does not roll over to zero.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Counter Roll Over</td> </tr> <tr> <td>0x1</td> <td>Counter does not Roll Over</td> </tr> </tbody> </table>	Value	Description	0x0	Counter Roll Over	0x1	Counter does not Roll Over	RW	0x0
Value	Description									
0x0	Counter Roll Over									
0x1	Counter does not Roll Over									
0	cntrst	<p>When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Auto cleared after 1 clock cycle</td> </tr> <tr> <td>0x1</td> <td>All Counters Reset</td> </tr> </tbody> </table>	Value	Description	0x0	Auto cleared after 1 clock cycle	0x1	All Counters Reset	RW	0x0
Value	Description									
0x0	Auto cleared after 1 clock cycle									
0x1	All Counters Reset									

MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

MMC_Transmit_Interrupt

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

MMC_Receive_Interrupt_Mask

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when the receive statistic counters reach half of their maximum value, or maximum value. This register is 32-bits wide.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF70010C
emac1	0xFF702000	0xFF70210C

Offset: 0x10C

Access: RW

MMC_Transmit_Interrupt_Mask

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or maximum value. This register is 32-bits wide.

MMC_IPC_Receive_Interrupt

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

L3_L4_Control0 Fields

Bit	Name	Description	Access	Reset
21	14dpim0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM0) is set high.	RW	0x0
20	14dpm0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	14spim0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 18 (L4SPM0) is set high.	RW	0x0
18	14spm0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0
16	14pen0	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM0 or L4DPM0 bit is set high.	RW	0x0

Bit	Name	Description	Access	Reset
15:11	l3hdbm0	IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM0, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
10:6	l3hsbm0	IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
5	l3daim0	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM0) is set high.	RW	0x0
4	l3dam0	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 2 (L3SAM0) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	l3saim0	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM0) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
2	l3sam0	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 4 (L3DAM0) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen0	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM0 or L3DAM0 bit is set high.	RW	0x0

Layer4_Address0

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

31:0	13a33	When Bit 0 (L3PEN3) and Bit 2 (L3SAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN3) and Bit 4 (L3DAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN3) is reset in Register 292 (Layer 3 and Layer 4 Control Register 3), this register is not used.	RW	0x0

Hash_Table_Reg0

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

VLAN_Hash_Table_Reg

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Sub_Second_Increment Fields

Bit	Name	Description	Access	Reset
7:0	ssinc	The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.	RW	0x0

System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to l3_sp_clk).

Module Instance	Base Address	Register Address

Target_Time_Nanoseconds Fields

Bit	Name	Description	Access	Reset
31	trgtbusy	The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.	RO	0x0
30:0	ttslo	This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSELO field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.	RW	0x0

Bit	Name	Description	Access	Reset
3:0	ppsctrl_ppscmd	<p>PPSCTRL0: PPS0 Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: -0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. -0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. -0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. -0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. -... -1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: *</p> <p>When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms * When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) * When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register). Flexible PPS0 Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The Software should ensure that these bits are programmed only when they are all-zero. The following list describes the values of PPSCMD0: *</p> <p>0000: No Command * 0001: START Single Pulse This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. * 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. * 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. * 0100: STOP Pulse train at</p>	RW	0x0

by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. * 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train

Auxiliary_Timestamp_Nanoseconds

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

PPS0_Width Fields

Bit	Name	Description	Access	Reset
31:0	ppswidth	These bits store the width between the rising edge and corresponding falling edge of the PPS0 signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20ns), and desired width between the rising and corresponding falling edges of PPS0 signal output is 80ns (that is, four units of sub-second increment value), then you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in Register 472 (PPS0 Interval Register).	RW	0x0

MAC_Address16_High

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address17_High

The MAC Address17 High register holds the upper 16 bits of the 18th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address17 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address19_High

The MAC Address19 High register holds the upper 16 bits of the 20th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address19 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address27 High register holds the upper 16 bits of the 28th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address27 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address30_High

The MAC Address30 High register holds the upper 16 bits of the 31th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address30 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 36th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address36_High

The MAC Address36 High register holds the upper 16 bits of the 37th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address36 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address38_High

The MAC Address38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address38 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address46 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 55th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address55_High

The MAC Address55 High register holds the upper 16 bits of the 56th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address55 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address57_High

The MAC Address57 High register holds the upper 16 bits of the 58th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address57 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address65 High register holds the upper 16 bits of the 66th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address65 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address68_High

The MAC Address68 High register holds the upper 16 bits of the 69th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address68 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 74th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address74_High

The MAC Address74 High register holds the upper 16 bits of the 75th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address74 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address76_High

The MAC Address76 High register holds the upper 16 bits of the 77th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address76 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address84 High register holds the upper 16 bits of the 85th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address84 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.
