MAC_Address86_High

The MAC Address86 High register holds the upper 16 bits of the 87th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address86 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address88_High

The MAC Address88 High register holds the upper 16 bits of the 89th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address88 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

31:0	addrlo	This field contains the lower 32 bits of the 97th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address97_High

The MAC Address97 High register holds the upper 16 bits of the 98th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address97 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address99_High

The MAC Address99 High register holds the upper 16 bits of the 100th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address99 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address105_High

The MAC Address105 High register holds the upper 16 bits of the 106th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address105 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address107_High

The MAC Address107 High register holds the upper 16 bits of the 108th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address107 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address110_High

The MAC Address110 High register holds the upper 16 bits of the 111th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address110 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address116_High

The MAC Address116 High register holds the upper 16 bits of the 117th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address116 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address118_High

The MAC Address118 High register holds the upper 16 bits of the 119th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address118 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address124_High

The MAC Address124 High register holds the upper 16 bits of the 125th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address124 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address125_Low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the 126th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF FFF

MAC_Address126_High

The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address126 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

DMA Register Group Register Descriptions

DMA Register Group

Offset: 0x1000

[Bus_Mode](#) on page 17-816

The Bus Mode register establishes the bus operating modes for the DMA.

[Transmit_Poll_Demand](#) on page 17-819

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

[Receive_Poll_Demand](#) on page 17-820

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

[Receive_Descriptor_List_Address](#) on page 17-821

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Transmit_Descriptor_List_Address on page 17-822

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Status on page 17-822

The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Operation_Mode on page 17-828

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Interrupt_Enable on page 17-834

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Missed_Frame_And_Buffer_Overflow_Counter on page 17-838

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Receive_Interrupt_Watchdog_Timer on page 17-839

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

AXI_Bus_Mode on page 17-840

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

AHB_or_AXI_Status on page 17-843

This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes.

Current_Host_Transmit_Descriptor on page 17-844

The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

Current_Host_Receive_Descriptor on page 17-844

The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

Current_Host_Transmit_Buffer_Address on page 17-845

The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

Current_Host_Receive_Buffer_Address on page 17-845

The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

HW_Feature on page 17-846

This register indicates the presence of the optional features or functions of the gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bus_Mode

The Bus Mode register establishes the bus operating modes for the DMA.

16	fb	<p>This bit controls whether the AXI Master interface performs fixed burst transfers or not. When set, the AXI interface uses FIXED bursts during the start of the normal burst transfers. When reset, the AXI interface uses SINGLE and INCR burst transfer operations. For more information, see Bit 0 (UNDEFINED) of the AXI Bus Mode register.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>SINGLE or INCR Burst</td> </tr> <tr> <td>0x1</td> <td>FIXED Burst (1, 4, 8, or 16)</td> </tr> </tbody> </table>	Value	Description	0x0	SINGLE or INCR Burst	0x1	FIXED Burst (1, 4, 8, or 16)	RW	0x0
Value	Description									
0x0	SINGLE or INCR Burst									
0x1	FIXED Burst (1, 4, 8, or 16)									
13:8	pbl	<p>These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: 1. Set the 8xPBL mode. 2. Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set 8xPBL to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified.</p>	RW	0x1						
7	atds	<p>When set, the size of the alternate (enhanced) descriptor increases to 32 bytes (8 DWORDS). When clear, the alternate (enhanced) descriptor size is 16 bytes (4 DWORDS).</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Descriptor size is 16 bytes (4 DWORDS)</td> </tr> <tr> <td>0x1</td> <td>Descriptor size is 32 bytes (8 DWORDS)</td> </tr> </tbody> </table>	Value	Description	0x0	Descriptor size is 16 bytes (4 DWORDS)	0x1	Descriptor size is 32 bytes (8 DWORDS)	RW	0x0

0x1	MAC DMA Controller Resets Logic									

Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Transmit_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	tpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.	RW	0x0

Receive_Poll_Demand

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Receive_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	rpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.	RW	0x0

Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Receive_Descriptor_List_Address Fields

Bit	Name	Description	Access	Reset
31:2	rdesla_32bit	This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

Transmit_Descriptor_List_Address

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Status

The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to

be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Bit	Name	Description	Access	Reset
16	nis	Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[0]: Transmit Interrupt * Register 5[2]: Transmit Buffer Unavailable * Register 5[6]: Receive Interrupt * Register 5[14]: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.	RW	0x0
15	ais	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.	RW	0x0
14	eri	This bit indicates that the DMA had filled the first data buffer of the packet. Bit 6 (RI) of this register automatically clears this bit.	RW	0x0
13	fbi	This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.	RW	0x0
10	eti	This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.	RW	0x0
9	rwt	This bit is asserted when a frame with length greater than 2,048 bytes is received (10,240 when Jumbo Frame mode is enabled).	RW	0x0
8	rps	This bit is asserted when the Receive Process enters the Stopped state.	RW	0x0

Bit	Name	Description	Access	Reset
7	ru	This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.	RW	0x0
6	ri	This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.	RW	0x0
5	unf	This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.	RW	0x0
4	ovf	This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].	RW	0x0
3	tjt	This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled) . When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.	RW	0x0
2	tu	This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.	RW	0x0
1	tps	This bit is set when the transmission is stopped.	RW	0x0

Bit	Name	Description	Access	Reset
0	ti	This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.	RW	0x0

Operation_Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Bit	Name	Description	Access	Reset										
13	st	<p>When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Transmission Stopped State</td> </tr> <tr> <td>0x1</td> <td>Transmission in Run State</td> </tr> </tbody> </table>	Value	Description	0x0	Transmission Stopped State	0x1	Transmission in Run State	RW	0x0

Bit	Name	Description	Access	Reset						
1	sr	<p>When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Register 3 (Receive Descriptor List Address Register) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Register 3 (Receive Descriptor List Address Register), the DMA behavior is unpredictable. When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Rx DMA operation is stopped</td> </tr> <tr> <td>0x1</td> <td>Rx DMA operation is started</td> </tr> </tbody> </table>	Value	Description	0x0	Rx DMA operation is stopped	0x1	Rx DMA operation is started	RW	0x0
Value	Description									
0x0	Rx DMA operation is stopped									
0x1	Rx DMA operation is started									

Interrupt_Enable

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Module Instance	Base Address	Register Address

Receive Interrupt Watchdog Timer Fields

Bit	Name	Description	Access	Reset
7:0	riwt	This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.	RW	0x0

AXI_Bus_Mode

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

Module Instance	Base Address	Register Address

1	blen4	<p>When this bit is set to 1, the GMAC-AXI is allowed to select a burst length of 4 on the AXI Master interface. Setting this bit has no effect when UNDEFINED is set to 1.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>AXI No Fixed Busrts</td> </tr> <tr> <td>0x1</td> <td>AXI Fixed Burst BLEN = 4</td> </tr> </tbody> </table>	Value	Description	0x0	AXI No Fixed Busrts	0x1	AXI Fixed Burst BLEN = 4	RW	0x0
Value	Description									
0x0	AXI No Fixed Busrts									
0x1	AXI Fixed Burst BLEN = 4									

Bit	Name	Description	Access	Reset						
0	undefined	<p>This bit is read-only bit and indicates the complement (invert) value of Bit 16 (FB) in Register 0 (Bus Mode Register[16]). * When this bit is set to 1, the GMAC-AXI is allowed to perform any burst length equal to or below the maximum allowed burst length programmed in Bits[7:1]. * When this bit is set to 0, the GMAC-AXI is allowed to perform only fixed burst lengths as indicated by BLEN16, BLEN8, or BLEN4, or a burst length of 1.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Fixed Burst Lengths 4 to 32</td> </tr> <tr> <td>0x1</td> <td>Any Burst Length up to max</td> </tr> </tbody> </table>	Value	Description	0x0	Fixed Burst Lengths 4 to 32	0x1	Any Burst Length up to max	RO	0x1
Value	Description									
0x0	Fixed Burst Lengths 4 to 32									
0x1	Any Burst Length up to max									

AHB_or_AXI_Status

This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF70102C
emac1	0xFF702000	0xFF70302C

The hard processor system (HPS) provides two instances of a USB On-The-Go (OTG) controller that supports both device and host functions. The controller supports all high-speed, full-speed, and low-speed transfers in both device and host modes. The controller is fully compliant with the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The controller can be programmed for both device and host functions to support data movement over the USB protocol.

The controllers are operationally independent of each other. Each USB OTG controller supports a single USB port connected through a USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) compliant PHY. The USB OTG controllers are instances of the Synopsys[®] ([†])DesignWare[®] Cores USB 2.0 Hi-Speed On-The-Go (DWC_otg) controller.

The USB OTG controller is optimized for the following applications and systems: †

- Portable electronic devices †
- Point-to-point applications (no hub, direct connection to HS, FS, or LS device) †
- Multi-point applications (as an embedded USB host) to devices (hub and split support) †

Each of the two USB OTG ports supports both host and device modes, as described in the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The USB OTG ports support connections for all types of USB peripherals, including the following peripherals:

- Mouse
- Keyboard
- Digital cameras
- Network adapters
- Hard drives
- Generic hubs

Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website

Features of the USB OTG Controller

The USB OTG controller has the following USB-specific features:

- Complies with both Revision 1.3 and Revision 2.0 of the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Supports all USB 2.0 speeds:
 - High speed (HS, 480-Mbps)
 - Full speed (FS, 12-Mbps)
 - Low speed (LS, 1.5-Mbps)

Note: In host mode, all speeds are supported. However, in device mode, only high speed and full speed are supported.

- Supports USB 2.0 in ULPI mode
- Supports all USB transaction types:
 - Control transfers
 - Bulk transfers
 - Isochronous transfers
 - Interrupts
- Supports automatic ping capability
- Supports Session Request Protocol (SRP) and Host Negotiation Protocol (HNP)
- Supports suspend, resume, and remote wake
- Supports up to 16 host channels

Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.

- Supports up to 16 bidirectional endpoints, including control endpoint 0

Note: Only seven periodic device IN endpoints are supported.

- Supports a generic root hub
- Performs transaction scheduling in hardware

On the USB PHY layer, the USB OTG controller supports the following features:

- A single USB port connected to each OTG instance
- A ULPI connection to an off-chip USB transceiver
- Software-controlled access, supporting vendor-specific or optional PHY registers access to ease debug
- The OTG 2.0 support for Attach Detection Protocol (ADP) only through an external (off-chip) ADP controller

On the integration side, the USB OTG controller supports the following features:

- Different clocks for system and PHY interfaces
- Dedicated TX FIFO buffer for each device IN endpoint in direct memory access (DMA) mode
- Packet-based, dynamic FIFO memory allocation for endpoints for small FIFO buffers and flexible, efficient use of RAM that can be dynamically sized by software
- Ability to change an endpoint's FIFO memory size during transfers
- Clock gating support during USB suspend and session-off modes
 - PHY clock gating support
 - System clock gating support
- Data FIFO RAM clock gating support
- Local buffering with error correction code (ECC) support

Note: The USB OTG controller does not support the following protocols:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)

Supported PHYS

The USB OTG controller only supports USB 2.0 ULPI PHYs. Only the single data rate (SDR) mode is supported.

PHYs that support LPM mode may not function properly with the USB controller due to a timing issue. It is recommended that designers use the MicroChip USB3300 PHY device that has been proven to be successful on the development board.

Refer to the *Cyclone[®] V Device Datasheet* for specific timing information.

USB OTG Controller Block Diagram and System Integration

Figure 18-1: USB OTG Controller System Integration

Two subsystems are included in the HPS.

The USB OTG controller connects to the level 3 (L3) interconnect through a slave interface, allowing other masters to access the control and status registers (CSRs) in the controller. The controller also connects to the L3 interconnect through a master interface, allowing the DMA engine in the controller to move data between external memory and the controller.

A single-port RAM (SPRAM) connected to the USB OTG controller is used to store USB data packets for both host and device modes. It is configured as FIFO buffers for receive and transmit data packets on the USB link.

Through the system manager, the USB OTG controller has control to use and test error correction codes (ECCs) in the SPRAM. Through the system manager, the USB OTG controller can also control the behavior of the master interface to the L3 interconnect.

The USB OTG controller connects to the external USB transceiver through a ULPI PHY interface. This interface also connects through pin multiplexers within the HPS. The pin multiplexers are controlled by the system manager.

Additional connections on the USB OTG controller include:

- Clock input from the clock manager to the USB OTG controller
- Reset input from the reset manager to the USB OTG controller
- Interrupt line from the USB OTG controller to the microprocessor unit (MPU) global interrupt controller (GIC).

The USB controller will only use Direct Shared IO 48.

Functional Description of the USB OTG Controller

USB OTG Controller Block Description

Figure 18-2: USB OTG Controller Block Description

Details about each of the units that comprise the USB OTG controller are shown below.

Master Interface

The master interface includes a built-in DMA controller. The DMA controller moves data between external memory and the media access controller (MAC).

Properties of the master interface are controlled through the USB L3 Master HPROT Register (`l3master`) in the system manager. These bits provide access information to the L3 interconnect, including whether or not transactions are cacheable, bufferable, or privileged.

Note: Bits in the `l3master` register can be updated only when the master interface is guaranteed to be in an inactive state.

Slave Interface

The slave interface allows other masters in the system to access the USB OTG controller's CSRs. For testing purposes, other masters can also access the SPRAM.

Slave Interface CSR Unit

The slave interface can read from and write to all the CSRs in the USB OTG controllers. All register accesses are 32 bits.

The CSR is divided into the following groups of registers:

- Global
- Host
- Device
- Power and clock gating

Some registers are shared between host and device modes, because the controller can only be in one mode at a time. The controller generates a mode mismatch interrupt if a master attempts to access device registers when the controller is in host mode, or attempts to access host registers when the controller is in device mode. Writing to unimplemented registers is ignored. Reading from unimplemented registers returns indeterminate values.

Application Interface Unit

The application interface unit (AIU) generates DMA requests based on programmable FIFO buffer thresholds. The AIU generates interrupts to the GIC for both host and device modes. A DMA scheduler is included in the AIU to arbitrate and control the data transfer between packets in system memory and their respective USB endpoints.

Packet FIFO Controller

The Packet FIFO Controller (PFC) connects the AIU with the MAC through data FIFO buffers located in the SPRAM. In device mode, one FIFO buffer is implemented for each IN endpoint. In host mode, a single FIFO buffer stores data for all periodic (isochronous and interrupt) OUT endpoints, and a single FIFO buffer is used for nonperiodic (control and bulk) OUT endpoints. Host and device mode share a single receive data FIFO buffer.

SPRAM

An SPRAM implements the data FIFO buffers for host and device modes. The size of the FIFO buffers can be programmed dynamically.

The SPRAM supports ECCs. ECCs can be enabled through the system manager, by setting the RAM ECC Enable (`en`) bit in the USB0 or USB1 RAM ECC Enable Register (`usb0` or `usb1`), in the ECC Management Register Group (`eccgrp`). Single-bit and double-bit errors in each USB instance can be injected using this register.

The SPRAM provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

MAC

The MAC module implements the following functionality:

- USB transaction support
- Host protocol support
- Device protocol support
- OTG protocol support
- Link power management (LPM) functions

USB Transactions

In device mode, the MAC decodes and checks the integrity of all token packets. For valid OUT or SETUP tokens, the following DATA packet is also checked. If the data packet is valid, the MAC performs the following steps:

1. Writes the data to the receive FIFO buffer
2. Sends the appropriate handshake when required to the USB host

If a receive FIFO buffer is not available, the MAC sends a NAK response to the host. The MAC also supports ping protocol.

For IN tokens, if data is available in the transmit FIFO buffer, the MAC performs the following steps:

1. Reads the data from the FIFO buffer
2. Forms the data packet
3. Transmits the packet to the host
4. Receives the response from the host
5. Sends the updated status to the PFC

In host mode, the MAC receives a token request from the AIU. The MAC performs the following steps:

1. Builds the token packet
2. Sends the packet to the device

For OUT or SETUP transactions, the MAC also performs the following steps:

1. Reads the data from the transmit FIFO buffer
2. Assembles the data packet
3. Sends the packet to the device
4. Waits for a response

The response from the device causes the MAC to send a status update to the AIU.

For IN or PING transactions, the MAC waits for the data or handshake response from the device. For data responses, the MAC performs the following steps:

1. Validates the data
2. Writes the data to the receive FIFO buffer
3. Sends a status update to the AIU
4. Sends a handshake to the device, if appropriate

Host Protocol

In host mode, the MAC performs the following functions:

- Detects connect, disconnect, and remote wakeup events on the USB link
- Initiates reset
- Initiates speed enumeration processes
- Generates Start of Frame (SOF) packets.

Device Protocol

In device mode, the MAC performs the following functions:

- Handles USB reset sequence
- Handles speed enumeration
- Detects USB suspend and resume activity on the USB link
- Initiates remote wakeup
- Decodes SOF packets

OTG Protocol

The MAC handles HNP and SRP for OTG operation. HNP provides a mechanism for swapping host and device roles. SRP provides mechanisms for the host to turn off V_{BUS} to save power, and for a device to request a new USB session.

LPM Functions

The USB OTG controller supports LPM in both host and device modes. With this feature, the USB OTG controller can enter a sleep state when a successful LPM transaction occurs on the USB link.

Wakeup and Power Control

To reduce power, the USB OTG controller supports a power-down mode. In power-down mode, the controller and the PHY can shut down their clocks. The controller supports wakeup on the detection of the following events:

- Resume
- Remote wakeup
- Session request protocol
- New session start

PHY Interface Unit

The USB OTG controller supports synchronous SDR data transmission to a ULPI PHY. The SDR mode implements an eight-bit data bus.

ULPI PHY Interface

Table 18-1: ULPI PHY Interfaces

The ULPI PHY interface is synchronous to the `ulpi_clk` signal coming from the PHY.

Port Name	Bit Width	Direction	Description
<code>ulpi_clk</code>	1	Input	ULPI Clock Receives the 60-MHz clock supplied by the high-speed ULPI PHY. All signals are synchronous to the positive edge of the clock.
<code>ulpi_dir</code>	1	Input	ULPI Data Bus Control 1—The PHY has data to transfer to the USB OTG controller. 0—The PHY does not have data to transfer.
<code>ulpi_nxt</code>	1	Input	ULPI Next Data Control Indicates that the PHY has accepted the current byte from the USB OTG controller. When the PHY is transmitting, this signal indicates that a new byte is available for the controller.
<code>ulpi_stp</code>	1	Output	ULPI Stop Data Control The controller drives this signal high to indicate the end of its data stream. The controller can also drive this signal high to request data from the PHY.
<code>ulpi_data[7:0]</code>	8	Bidirectional	Bidirectional data bus. Driven low by the controller during idle.

Local Memory Buffer

The NAND flash controller has three local SRAM memory buffers.

- The write FIFO buffer is a 128 × 32-bit memory (512 total bytes)
- The read FIFO buffer is a 32 × 32-bit memory (128 total bytes)
- The ECC buffer is a 96 × 16-bit memory (1536 total bytes)

The SPRAM is a 8192 × 35-bit (32 data bits and 3 control bits) memory and includes support for ECC (Error Checking and Correction). The ECC block is integrated around a memory wrapper. It provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes. The ECC feature is disabled by default. It must be initialized to enable the ECC function.

Clocks

Table 18-2: USB OTG Controller Clock Inputs

All clocks must be operational when reset is released. No special handling is required on the clocks.

Clock Signal	Frequency	Functional Usage
usb_mp_clk	60 – 200 MHz	Drives the master and slave interfaces, DMA controller, and internal FIFO buffers
usb0_ulpi_clk	60 MHz	ULPI reference clock for usb0 from external ULPI PHY I/O pin
usb1_ulpi_clk	60 MHz	ULPI reference clock for usb1 from external ULPI PHY I/O pin

Resets

The USB OTG controller can be reset either through the hardware reset input or through software.

Reset Requirements

There must be a minimum of 12 cycles on the `ulpi_clk` clock before the controller is taken out of reset. During reset, the USB OTG controller asserts the `ulpi_stp` signal. The PHY outputs a clock when it sees the `ulpi_stp` signal asserted. However, if the pin multiplexers are not programmed, the PHY does not see the `ulpi_stp` signal. As a result, the `ulpi_clk` clock signal does not arrive at the USB OTG controller.

Software must ensure that the reset is active for a minimum of two `usb_mp_clk` cycles. There is no maximum assertion time.

Hardware Reset

Each of the USB OTG controllers has one reset input from the reset manager. The reset signal is asserted during a cold or warm reset event. The reset manager holds the controllers in reset until software releases the resets. Software releases resets by clearing the appropriate USB bits in the Peripheral Module Reset Register (`permodrst`) in the HPS reset manager.

The reset input resets the following blocks:

- The master and slave interface logic
- The integrated DMA controller
- The internal FIFO buffers
- The CSR

The reset input is synchronized to the `usb_mp_clk` domain. The reset input is also synchronized to the ULPI clock within the USB OTG controller and is used to reset the ULPI PHY domain logic.

Software Reset

Software can reset the controller by setting the Core Soft Reset (`csftrst`) bit in the Reset Register (`grstctl`) in the Global Registers (`globgrp`) group of the USB OTG controller.

Software resets are useful in the following situations:

- A PHY selection bit is changed by software. Resetting the USB OTG controller is part of clean-up to ensure that the PHY can operate with the new configuration or clock.
- During software development and debugging.

Taking the USB 2.0 OTG Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

[Modules Requiring Software Deassert](#) on page 3-9

Interrupts

Table 18-3: USB OTG Interrupt Conditions

Each USB OTG controller has a single interrupt output. Interrupts are asserted on the conditions shown in the following table.

Condition	Mode
Device-initiated remote wakeup is detected.	Host mode
Session request is detected from the device.	Host mode
Device disconnect is detected.	Host mode
Host LPM entry retry has expired or LPM transaction(s) are complete.	Host mode
Host periodic TX FIFO buffer is empty (can be further programmed to indicate half-empty).	Host mode
Host channels interrupt received.	Host mode
Incomplete periodic transfer is pending at the end of the microframe.	Host mode
Host port status interrupt received.	Host mode
External host initiated resume is detected.	Device mode
LPM handshake is sent.	Device mode
Reset is detected when in suspend or normal mode.	Device mode
USB suspend mode is detected.	Device mode

Condition	Mode
Data fetch is suspended due to TX FIFO buffer full or request queue full.	Device mode
At least one isochronous OUT endpoint is pending at the end of the microframe.	Device mode
At least one isochronous IN endpoint is pending at the end of the microframe.	Device mode
At least one IN or OUT endpoint interrupt is pending at the end of the microframe.	Device mode
The end of the periodic frame is reached.	Device mode
Failure to write an isochronous OUT packet to the RX FIFO buffer. The RX FIFO buffer does not have enough space to accommodate the maximum packet size for the isochronous OUT endpoint.	Device mode
Enumeration has completed.	Device mode
Connector ID change.	Common modes
Mode mismatch. Software accesses registers belonging to an incorrect mode.	Common modes
Nonperiodic TX FIFO buffer is empty.	Common modes
RX FIFO buffer is not empty.	Common modes
Start of microframe.	Common modes
Device connection debounce is complete in host mode.	OTG interrupts
A-Device timeout while waiting for B-Device connection.	OTG interrupts
Host negotiation is complete.	OTG interrupts
Session request is complete.	OTG interrupts
Session end is detected in device mode.	OTG interrupts

USB OTG Controller Programming Model

For detailed information about using the USB OTG controller, consult your operating system (OS) driver documentation. The OS vendor provides application programming interfaces (APIs) to control USB host, device and OTG operation. This section provides a brief overview of the following software operations:

- Enabling SPRAM ECCs
- Host operation
- Device operation

Enabling SPRAM ECCs

To avoid false ECC errors, you must initialize the ECC bits in the SPRAM before using ECCs. To initialize the ECC bits, software writes data to all locations in the SPRAM.

The L3 interconnect has access to the SPRAM and is accessible through the USB OTG L3 slave interface. Software accesses the SPRAM through the `directfifo` memory space, in the USB OTG controller address space.

The SPRAM contains 8192 (32 KB) locations. The L3 slave provides 32-bit access to the SPRAM. Physically, the SPRAM is implemented as a 35-bit memory, with the highest three bits reserved for the USB OTG controller's internal use. When a write is performed to the SPRAM through the L3 slave interface, bits 32 through 34 of the internal data bus are tied to 1, to enable the ECC bits to be initialized.

Note: Software cannot access the SPRAM beyond the 32-KB range. Out-of-range read transactions return indeterminate data. Out-of-range write transactions are ignored.

Host Operation

Host Initialization

After power up, the USB port is in its default mode. No VBUS is applied to the USB cable. The following process sets up the USB OTG controller as a USB host.

1. To enable power to the USB port, the software driver sets the Port Power (`prtppwr`) bit to 1 in the Host Port Control and Status Register (`hpprt`) of the Host Mode Registers (`hostgrp`) group. This action drives the V_{BUS} signal on the USB link.

The controller waits for a connection to be detected on the USB link.

2. When a USB device connects, an interrupt is generated. The Port Connect Detected (`prtConnDe t`) bit in `hpprt` is set to 1.
3. Upon detecting a port connection, the software driver initiates a port reset by setting the Port Reset (`prtrst`) bit to 1 in `hpprt`.
4. The software driver must wait a minimum of 10 ms so that speed enumeration can complete on the USB link.
5. After the 10 ms, the software driver sets `prtrst` back to 0 to release the port reset.
6. The USB OTG controller generates an interrupt. The Port Enable Disable Change (`prtENCHng`) and Port Speed (`prtspd`) bits, in `hpprt`, are set to reflect the enumerated speed of the device that attached.

At this point the port is enabled for communication. Keep alive or SOF packets are sent on the port. If a USB 2.0-capable device fails to initialize correctly, it is reported as a USB 1.1 device.

The Host Frame Interval Register (`hfir`) is updated with the corresponding PHY clock settings. The `hfir`, used for sending SOF packets, is in the Host Mode Registers (`host grp`) group.

7. The software driver must program the following registers in the Global Registers (`globgrp`) group, in the order listed:
 - a. Receive FIFO Size Register (`grxfsiz`)—selects the size of the receive FIFO buffer
 - b. Non-periodic Transmit FIFO Size Register (`gnptxfsiz`)—selects the size and the start address of the non-periodic transmit FIFO buffer for nonperiodic transactions
 - c. Host Periodic Transmit FIFO Size Register (`hptxfsiz`)—selects the size and start address of the periodic transmit FIFO buffer for periodic transactions
8. System software initializes and enables at least one channel to communicate with the USB device.

Host Transaction

When configured as a host, the USB OTG controller pipes the USB transactions through one of two request queues (one for periodic transactions and one for nonperiodic transactions). Each entry in the request queue holds the SETUP, IN, or OUT channel number along with other information required to perform a transaction on the USB link. The sequence in which the requests are written to the queue determines the sequence of transactions on the USB link.

The host processes the requests in the following order at the beginning of each frame or microframe:

1. Periodic request queue, including isochronous and interrupt transactions
2. Nonperiodic request queue (bulk or control transfers)

The host schedules transactions for each enabled channel in round-robin fashion. When the host controller completes the transfer for a channel, the controller updates the DMA descriptor status in the system memory.

For OUT transactions, the host controller uses two transmit FIFO buffers to hold the packet payload to be transmitted. One transmit FIFO buffer is used for all nonperiodic OUT transactions and the other is used for all periodic OUT transactions.

For IN transactions, the USB host controller uses one receive FIFO buffer for all periodic and nonperiodic transactions. The controller holds the packet payload from the USB device in the receive FIFO buffer until the packet is transferred to the system memory. The receive FIFO buffer also holds the status of each packet received. The status entry holds the IN channel number along with other information, including received byte count and validity status.

For generic hub operations, the USB OTG controller uses SPLIT transfers to communicate with slower-speed devices downstream of the hub. For these transfers, the transaction accumulation or buffering is performed in the generic hub, and is scheduled accordingly. The USB OTG controller ensures that enough transmit and receive buffers are allocated when the downstream transactions are completed or when accumulated data is ready to be sent upstream.

Device Operation

Device Initialization

The following process sets up the USB OTG controller as a USB device:

1. After power up, the USB OTG controller must be set to the desired device speed by writing to the Device Speed (`devspd`) bits in the Device Configuration Register (`dconfg`) in the Device Mode Registers

(`devgrp`) group. After the device speed is set, the controller waits for a USB host to detect the USB port as a device port.

2. When an external host detects the USB port, the host performs a port reset, which generates an interrupt to the USB device software. The USB Reset (`usbrst`) bit in the Interrupt (`port reset`) register in the Global Registers (`globgrp`) group is set. The device software then sets up the data FIFO buffer to receive a SETUP packet from the external host. Endpoint 0 is not enabled yet.
3. After completion of the port reset, the operation speed required by the external host is known. Software reads the device speed status and sets up all the remaining required transaction fields to enable control endpoint 0.

After completion of this process, the device is receiving SOF packets, and is ready for the USB host to set up the device's control endpoint.

Device Transaction

When configured as a device, the USB OTG controller uses a single FIFO buffer to receive the data for all the OUT endpoints. The receive FIFO buffer holds the status of the received data packet, including the byte count, the data packet ID (PID), and the validity of the received data. The DMA controller reads the data out of the FIFO buffer as the data are received. If a FIFO buffer overflow condition occurs, the controller responds to the OUT packet with a NAK, and internally rewinds the pointers.

For IN endpoints, the controller uses dedicated transmit buffers for each endpoint. The application does not need to predict the order in which the USB host will access the nonperiodic endpoints. If a FIFO buffer underrun condition occurs during transmit, the controller inverts the cyclic redundancy code (CRC) to mark the packet as corrupt on the USB link.

The application handles one data packet at a time per endpoint in transaction-level operations. The software receives an interrupt on completion of every packet. Based on the handshake response received on the USB link, the application determines whether to retry the transaction or proceed with the next transaction, until all packets in the transfer are completed.

IN Transactions

For an IN transaction, the application performs the following steps:

1. Enables the endpoint
2. Triggers the DMA engine to write the associated data packet to the corresponding transmit FIFO buffer
3. Waits for the packet completion interrupt from the controller

When an IN token is received on an endpoint when the associated transmit FIFO buffer does not contain sufficient data, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to the USB host

If sufficient data is available, the controller transmits the data to the USB host.

OUT Transactions

For an OUT transaction, the application performs the following steps:

1. Enables the endpoint
2. Waits for the packet received interrupt from the USB OTG controller
3. Retrieves the packet from the receive FIFO buffer

When an OUT token or PING token is received on an endpoint where the receive FIFO buffer does not have sufficient space, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to USB host

If sufficient space is available, the controller stores the data in the receive FIFO buffer and returns an ACK handshake to the USB link.

Control Transfers

For control transfers, the application performs the following steps:

1. Waits for the packet received interrupt from the controller
2. Retrieves the packet from the receive buffer

Because the control transfer is governed by USB protocol, the controller always responds with an ACK handshake.

USB OTG Controller Address Map and Register Definitions

The address map and register definitions for the USB OTG Controller consists of the following region:

USB OTG Controller Module Registers Address Map on page 18-16

Registers in the USB OTG Controller Module. Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessed in both Host and Device modes. When the USB OTG Controller is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (GINTSTS.ModeMis). When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset. The register address map is fixed and does not depend on the module configuration (for example, how many endpoints are implemented). Host and Device mode registers occupy different addresses.

- **Introduction to the Cyclone V Hard Processor System** on page 1-1
The base addresses of all modules are listed in the *Introduction to the Hard Processor System* chapter.
- <http://www.altera.com/literature/hb/cyclone-v/hps.html>

USB OTG Controller Module Registers Address Map

Registers in the USB OTG Controller Module. Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessed in both Host and Device modes. When the USB OTG Controller is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the

Core Interrupt register (GINTSTS.ModeMis). When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset. The register address map is fixed and does not depend on the module configuration (for example, how many endpoints are implemented). Host and Device mode registers occupy different addresses.

Module Instance	Base Address
usb0	0xFFB00000
usb1	0xFFB40000

Global Registers

Register	Offset	Width	Access	Reset Value	Description
gotgctl on page 18-40	0x0	32	RW	0x10000	OTG Control and Status Register

Direct_FIFO	This address space is allocated for directly accessing the data FIFO for debugging purposes.	0x20000	0x3FFFF

Global Registers Register Descriptions

These registers are available in both Host and Device modes, and do not need to be reprogrammed when switching between these modes.

Offset: 0x0

gotgctl on page 18-40

The OTG Control and Status register controls the behavior and reflects the status of the OTG function.

gotgint on page 18-45

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

gahbcfg on page 18-47

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

gusbcfg on page 18-51

This register can be used to configure the core after power-on or a changing to Host mode or Device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

grstctl on page 18-57

The application uses this register to reset various hardware features inside the core

gintsts on page 18-61

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

gintmsk on page 18-70

This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstsr on page 18-75

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the Rx FIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxstsp on page 18-76

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the Rx FIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

grxfsiz on page 18-77

The application can program the RAM size that must be allocated to the Rx FIFO.

gnptxsiz on page 18-78

The application can program the RAM size and the memory start address for the Non-periodic Tx FIFO. The fields of this register change, depending on host or device mode.

gnptxsts on page 18-79

In Device mode, this register is valid only in Shared FIFO operation. It contains the free space information for the Non-periodic Tx FIFO and the Non-periodic Transmit Request Queue

gpvndctl on page 18-80

The application can use this register to access PHY registers. For a ULPI PHY, the core uses the ULPI interface for PHY register access. The application sets Vendor Control register for PHY register access and times the PHY register access. The application polls the VStatus Done bit in this register for the completion of the PHY register access

ggpio on page 18-82

The application can use this register for general purpose input/output ports or for debugging.

guid on page 18-83

This is a read/write register containing the User ID. This register can be used in the following ways: -To store the version or revision of your system -To store hardware configurations that are outside the otg core As a scratch register

gsnpsid on page 18-84

This read-only register contains the release number of the core being used.

ghwcfg1 on page 18-84

This register contains the logical endpoint direction(s).

ghwcfg2 on page 18-85

This register contains configuration options.

ghwcfg3 on page 18-89

This register contains the configuration options.

ghwcfg4 on page 18-91

This register contains the configuration options.

gdfifocfg on page 18-96

Specifies whether Dedicated Transmit FIFOs should be enabled in device mode.

hptxsiz on page 18-96

This register holds the size and the memory start address of the Periodic TxFIFO

dieptxf1 on page 18-97

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for each instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf2 on page 18-98

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

dieptxf3 on page 18-99

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFO. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

Value	Description									
0x0	PHY 8bit Mode									

Bit	Name	Description	Access	Reset
2:0	toutcal	Mode:Host and Device. The number of PHY clocks that the application programs in this field is added to the high-speed/full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the linestate condition can vary from one PHY to another. The USB standard timeout value for high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock are: High-speed operation: -One 30-MHz PHY clock = 16 bit times -One 60-MHz PHY clock = 8 bit times Full-speed operation: -One 30-MHz PHY clock = 0.4 bit times -One 60-MHz PHY clock = 0.2 bit times -One 48-MHz PHY clock = 0.25 bit times	RW	0x0

Bit	Name	Description	Access	Reset						
5	txfflsh	<p>Mode:Host and Device. This bit selectively flushes a single or all transmit FIFOs, but cannot do so If the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers: ReadNAK Effective Interrupt ensures the core is notreading from the FIFO WriteGRSTCTL.AHBIdle ensures the core is not writinganything to the FIFO. Flushing is normally recommended when FIFOs are reconfigured or when switching between Shared FIFO and Dedicated Transmit FIFO operation. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Flush</td> </tr> <tr> <td>0x1</td> <td>selectively flushes a single or all transmit FIFOs</td> </tr> </tbody> </table>	Value	Description	0x0	No Flush	0x1	selectively flushes a single or all transmit FIFOs	RO	0x0
Value	Description									
0x0	No Flush									
0x1	selectively flushes a single or all transmit FIFOs									
4	rxfflsh	<p>Mode:Host and Device. The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction. The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO. The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>no flush the entire RxFIFO</td> </tr> <tr> <td>0x1</td> <td>flush the entire RxFIFO</td> </tr> </tbody> </table>	Value	Description	0x0	no flush the entire RxFIFO	0x1	flush the entire RxFIFO	RO	0x0

Bit	Name	Description	Access	Reset						
0	csftrst	<p>Mode:Host and Device. Resets the hclk and phy_clock domains as follows:Clears the interrupts and all the CSR registers except the following register bits: - PCGCCTL.RstPdownModule - PCGCCTL.GateHclk - PCGCCTL.PwrClmp - PCGCCTL.StopPPhyLPwrClkSelclk - GUSBCFG.PhyLPwrClkSel - GUSBCFG.DDRSel - GUSBCFG.PHYSel - GUSBCFG.FSIntf - GUSBCFG.ULPI_UTMI_Sel - GUSBCFG.PHYIf - HCFG.FSLSPclkSel - DCFG.DevSpd - GGPIO - GPWRDN - GADPCTL All module state machines (except the AHB Slave Unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed. Any transactions on the AHB Master are terminated as soonas possible, after gracefully completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. When Hibernation or ADP feature is enabled, the PMU module is not reset by the Core Soft Reset.The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (AHB Master is IDLE) before starting any operation.Typically software reset is used during software development and also when you dynamically change the PHY selection bits in the USB configuration registers listed above. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No reset</td> </tr> <tr> <td>0x1</td> <td>Resets hclk and phy_clock domains</td> </tr> </tbody> </table>	Value	Description	0x0	No reset	0x1	Resets hclk and phy_clock domains	RO	0x0
Value	Description									
0x0	No reset									
0x1	Resets hclk and phy_clock domains									

gintsts

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type R_SS_WC, the application must write 1 into the bit. The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared

automatically. The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

gintmsk

This register works with the Interrupt Register (GINTSTS) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

grxstsr

A read to the Receive Status Read and Pop register additionally pops the: top data entry out of the Rx FIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLvl) is asserted. Use of these fields vary based on whether the HS OTG core is functioning as a host or a device. Do not read this register's reset value before configuring the core because the read value is "X" in the simulation.

0x1	Register Write									
21:16	regaddr	The 6-bit PHY register address for immediate PHY Register Set access. Set to 0x2F for Extended PHY Register Set access.	RW	0x0						
15:8	vctrl	The 4-bit register address a vendor defined 4-bit parallel output bus. ULPI Extended Register Address and the 6-bit PHY extended register address.	RW	0x0						
7:0	regdata	Contains the write data for register write. Read data for register read, valid when VStatus Done is Set.	RW	0x0						

ggpio

The application can use this register for general purpose input/output ports or for debugging.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00038
usb1	0xFFB40000	0xFFB40038

Offset: 0x38

Access: RW

gpo RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
gpi RO 0x0															

ggpio Fields

Bit	Name	Description	Access	Reset
31:16	gpo	This field is driven as an output from the core, gp_o[15:0]. The application can program this field to determine the corresponding value on the gp_o[15:0] output.	RW	0x0
15:0	gpi	This field's read value reflects the gp_i[15:0] core input value.	RO	0x0

guid

This is a read/write register containing the User ID. This register can be used in the following ways: -To store the version or revision of your system -To store hardware configurations that are outside the otg core As a scratch register

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB0003C

Host Mode Registers Register Descriptions

These registers must be programmed every time the USB OTG Controller changes to Host mode.

Offset: 0x400

hcfg on page 18-118

Host Mode control. This register must be programmed every time the core changes to Host mode

hfir on page 18-121

This register stores the frame interval information for the current speed to which the otg core has enumerated

hfnum on page 18-122

This register contains the free space information for the Periodic Tx FIFO and the Periodic Transmit Request Queue

hptxsts on page 18-123

This register contains the free space information for the Periodic Tx FIFO and the Periodic Transmit Request Queue.

haint on page 18-125

When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel-n Interrupt register.

haintmsk on page 18-126

The Host All Channel Interrupt Mask register works with the Host All Channel Interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

hflbaddr on page 18-127

This Register is valid only for Host mode Scatter-Gather DMA. Starting address of the Frame list. This register is used only for Isochronous and Interrupt Channels.

hpri on page 18-127

This register is available only in Host mode. Currently, the OTG Host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. The R_SS_WC bits in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. For the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt.

hcchar0 on page 18-132

Channel_number: 0.

hcsplt0 on page 18-135

Channel_number 0

hcint0 on page 18-137

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk0 on page 18-141

This register reflects the mask for each channel status described in the previous section.

hctsiz0 on page 18-142

Buffer DMA Mode

hcdma0 on page 18-144

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab0 on page 18-145

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar1 on page 18-146

Host Channel 1 Characteristics Register

hcsplt1 on page 18-149

Channel_number 1

hcint1 on page 18-151

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk1 on page 18-155

This register reflects the mask for each channel status described in the previous section.

hctsiz1 on page 18-156

Buffer DMA Mode

hcdma1 on page 18-158

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdmab1 on page 18-159

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcchar2 on page 18-160

Host Channel 2 Characteristics Register

hcsplt2 on page 18-163

Channel_number 2

hcint2 on page 18-165

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcintmsk2 on page 18-169

This register reflects the mask for each channel status described in the previous section.

hctsiz2 on page 18-170

Buffer DMA Mode.

hcdma2 on page 18-172

haint

When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt).

There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel-n Interrupt register.

hprt

This register is available only in Host mode. Currently, the OTG Host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. The R_SS_WC bits in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. For the R_SS_WC bits, the application must write a 1 to the bit to clear the interrupt.

hcint0

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

28:19	pktcnt	<p>This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.</p>	RW	0x0										

Bit	Name	Description	Access	Reset
18:0	xfersize	For an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma0

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma0 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma0	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab0

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint1

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma1 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma1	<p>Non-Isynchronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab1

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint2

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma2 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma2	<p>Non-Isynchronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab2

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint3

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma3 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma3	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2 \times (nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8\text{bytes} \times 5) = 40(\text{decimal})$ to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab3

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. hcint4

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma4 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma4	Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.	RW	0x0

hcdmab4

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint5

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma5 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma5	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2 \times (nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8\text{bytes} \times 5) = 40(\text{decimal})$ to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab5

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint6

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma6 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma6	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2 \times (nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8\text{bytes} \times 5) = 40(\text{decimal})$ to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab6

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint7

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

31:0	hcdma7	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2 \times (nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcint8

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

28:19	pktcnt	<p>This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.</p>	RW	0x0										

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma8

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma8 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma8	<p>Non-Isynchronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2 \times (nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8\text{bytes} \times 5) = 40(\text{decimal})$ to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab8

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint9

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma9 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma9	<p>Non-Isynchronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab9

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint10

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

28:19	pktcnt	<p>This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.</p>	RW	0x0										

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma10

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma10 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma10	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab10

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint11

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

28:19	pktcnt	<p>This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.</p>	RW	0x0										

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).The width of this counter is specified as 19 bits.	RW	0x0

hcdma11

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma11 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma11	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab11

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint12

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma12 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma12	<p>Non-Isynchronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2 \times (nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8\text{bytes} \times 5) = 40(\text{decimal})$ to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab12

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint13

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

hcdma13 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma13	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the $2 \times (nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of $(8\text{bytes} \times 5) = 40(\text{decimal})$ to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab13

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcdmab13 Fields

Bit	Name	Description	Access	Reset
31:0	hcdmab13	These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.	RW	0x0

hcint14

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

28:19	pktcnt	<p>This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as 10 bits.</p>	RW	0x0										

Bit	Name	Description	Access	Reset
18:0	xfersize	for an OUT, this field is the number of data bytes the host sends during the transfer. for an IN, this field is the buffer size that the application has Reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). The width of this counter is specified as 19 bits.	RW	0x0

hcdma14

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

hcdma14 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma14	<p>Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC FS ISOC nTD N nTD N 7 6 1 4 15 7 3 5 31 8 7 6 63 9 15 7 127 10 31 8 255 11 63 9 [N-1:3] (Isoc):[8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. for example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/microframe value. Need to be set to zero by application.</p>	RW	0x0

hcdmab14

These registers are present only in case of Scatter/Gather DMA. These registers are implemented in RAM instead of flop-based implementation. Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode. Otherwise this field is reserved.

hcint15

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

RW	0x0

Device Mode Registers Register Descriptions

These registers must be programmed every time the USB OTG Controller changes to Device mode.

Offset: 0x800

dcfg on page 18-370

This register configures the core in Device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

dctl on page 18-373

dsts on page 18-378

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from Device All Interrupts (DAINT) register.

diepmsk on page 18-380

This register works with each of the Device IN Endpoint Interrupt (DIEPINT_n) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the DIEPINT_n register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

doepmsk on page 18-382

This register works with each of the Device OUT Endpoint Interrupt (DOEPINT_n) registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the DOEPINT_n register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

daint on page 18-384

When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively). This is shown in Figure 5-2. There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINT_n/DOEPINT_n).

daintmsk on page 18-390

The Device Endpoint Interrupt Mask register works with the Device Endpoint Interrupt register to interrupt the application when an event occurs on a device endpoint. However, the Device All Endpoints Interrupt (DAINT) register bit corresponding to that interrupt is still set.

dvbusdis on page 18-395

This register specifies the VBUS discharge time after VBUS pulsing during SRP.

dvbuspulse on page 18-395

This register specifies the VBUS pulsing time during SRP.

dthrcctl on page 18-396

Thresholding is not supported in Slave mode and so this register must not be programmed in Slave mode. For threshold support, the AHB must be run at 60 MHz or higher.

diepempmsk on page 18-399

This register is used to control the IN endpoint FIFO empty interrupt generation (DIEPINTn.TxfEmp).

diepctl0 on page 18-402

This register covers Device Control IN Endpoint 0.

diepint0 on page 18-405

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz0 on page 18-409

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

diepdma0 on page 18-410

DMA Addressing.

dtxfsts0 on page 18-411

This register contains the free space information for the Device IN endpoint Tx FIFO.

diepdma0 on page 18-411

Endpoint 16.

diepctl1 on page 18-412

Endpoint_number: 1

diepint1 on page 18-418

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz1 on page 18-422

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma1 on page 18-423

DMA Addressing.

dtxfsts1 on page 18-424

This register contains the free space information for the Device IN endpoint TxFIFO.

diepdma1 on page 18-425

DMA Buffer Address.

diepctl2 on page 18-425

Endpoint_number: 2

diepint2 on page 18-431

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz2 on page 18-435

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma2 on page 18-436

DMA Addressing.

DTXFSTS2 on page 18-437

diepint14 on page 18-587

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz14 on page 18-591

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma15 on page 18-607

DMA Buffer Address.

doepctl0 on page 18-608

This is Control OUT Endpoint 0 Control register.

doepint0 on page 18-610

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doeptsiz0 on page 18-614

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

0x1	No Mask Transfer Completed Interrupt									

daint

When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPIInt or GINTSTS.IEPIInt, respectively). This is shown in Figure 5-2.

There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINTn/DOEPINTn).

daintmsk

The Device Endpoint Interrupt Mask register works with the Device Endpoint Interrupt register to interrupt the application when an event occurs on a device endpoint. However, the Device All Endpoints Interrupt (DAINT) register bit corresponding to that interrupt is still set.

dvbusdis Fields

Bit	Name	Description	Access	Reset
15:0	dvbusdis	This value equals: VBUS discharge time in PHY clocks/1,024 The value you use depends whether the PHY is operating at 30 MHz (16-bit data width) or 60 MHz (8-bit data width). Depending on your VBUS load, this value can need adjustment.	RW	0x17D7

dvbuspulse

This register specifies the VBUS pulsing time during SRP.

11:0	dvbuspulse	Specifies the VBUS pulsing time during SRP. This value equals: VBUS pulsing time in PHY clocks/1,024 The value you use depends whether the PHY is operating at 30MHz (16-bit data width) or 60 MHz (8-bit data width).	RW	0x5B8

dthrctl

Thresholding is not supported in Slave mode and so this register must not be programmed in Slave mode. for threshold support, the AHB must be run at 60 MHz or higher.

dthrctl Fields

Bit	Name	Description	Access	Reset
27	arbprken	<p>This bit controls internal DMA arbiter parking for IN endpoints. When thresholding is enabled and this bit is Set to one, Then the arbiter parks on the IN endpoint for which there is a token received on the USB. This is done to avoid getting into underrun conditions. By Default the parking is enabled.</p> <p>Value Description</p> <p>0x0 Disable DMA arbiter parking</p> <p>0x1 Enable DMA arbiter parking for IN endpoints</p>	RW	0x1
25:17	rxthrlen	<p>This field specifies Receive thresholding size in DWORDS.This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight DWORDS. The recommended value for ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).</p>	RW	0x8
16	rxthren	<p>When this bit is Set, the core enables thresholding in the receive direction.</p> <p>Value Description</p> <p>0x0 Disable thresholding</p> <p>0x1 Enable thresholding in the receive direction</p>	RW	0x0

Bit	Name	Description	Access	Reset										
12:11	ahbthrratio	<p>These bits define the ratio between the AHB threshold and the MAC threshold for the transmit path only. The AHB threshold always remains less than or equal to the USB threshold, because this does not increase overhead. Both the AHB and the MAC threshold must be DWORD-aligned. The application needs to program TxThrLen and the AHBThrRatio to make the AHB Threshold value DWORD aligned. If the AHB threshold value is not DWORD aligned, the core might not behave correctly. When programming the TxThrLen and AHBThrRatio, the application must ensure that the minimum AHB threshold value does not go below 8 DWORDS to meet the USB turnaround time requirements.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>AHB threshold = MAC threshold</td> </tr> <tr> <td>0x1</td> <td>AHB threshold = MAC threshold /2</td> </tr> <tr> <td>0x2</td> <td>AHB threshold = MAC threshold /4</td> </tr> <tr> <td>0x3</td> <td>AHB threshold = MAC threshold /</td> </tr> </tbody> </table>	Value	Description	0x0	AHB threshold = MAC threshold	0x1	AHB threshold = MAC threshold /2	0x2	AHB threshold = MAC threshold /4	0x3	AHB threshold = MAC threshold /	RW	0x0
Value	Description													
0x0	AHB threshold = MAC threshold													
0x1	AHB threshold = MAC threshold /2													
0x2	AHB threshold = MAC threshold /4													
0x3	AHB threshold = MAC threshold /													
10:2	txthrlen	<p>This field specifies Transmit thresholding size in DWORDS. This also forms the MAC threshold and specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmit on the USB. The threshold length has to be at least eight DWORDS when the value of AHBThrRatio is 0. In case the AHBThrRatio is non zero the application needs to ensure that the AHB Threshold value does not go below the recommended eight DWORD. This field controls both isochronous and non-isochronous IN endpoint thresholds. The recommended value for ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).</p>	RW	0x8										
1	isothren	<p>When this bit is Set, the core enables thresholding for isochronous IN endpoints.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No thresholding</td> </tr> <tr> <td>0x1</td> <td>Enables thresholding</td> </tr> </tbody> </table>	Value	Description	0x0	No thresholding	0x1	Enables thresholding	RW	0x0				
Value	Description													
0x0	No thresholding													
0x1	Enables thresholding													

Bit	Name	Description	Access	Reset						
0	nonisothren	When this bit is Set, the core enables thresholding for Non Isochronous IN endpoints. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No thresholding</td> </tr> <tr> <td>0x1</td> <td>Enable thresholding</td> </tr> </tbody> </table>	Value	Description	0x0	No thresholding	0x1	Enable thresholding	RW	0x0
Value	Description									
0x0	No thresholding									
0x1	Enable thresholding									

diepempmsk

This register is used to control the IN endpoint FIFO empty interrupt generation (DIEPINTn.TxfEmp).

diepint0

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

dieptsiz0

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

dieptsiz0 Fields

Bit	Name	Description	Access	Reset
20:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
6:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma0 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma0	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst0

diepint1

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset						
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - for IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - for OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.	RO	0x0						
		<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt		
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

dieptsiz1

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma1 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma1	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst1

Bit	Name	Description	Access	Reset										
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0										
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>STALL All Tokens not active</td> </tr> <tr> <td>0x1</td> <td>STALL All Tokens active</td> </tr> </tbody> </table>	Value	Description	0x0	STALL All Tokens not active	0x1	STALL All Tokens active	RO	0x0

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint2

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz2

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma2 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma2	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

DTXFSTS2

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint3

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz3

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma3 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma3	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst3

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint4

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz4

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma4 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma4	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst4

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint5

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz5

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma5 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma5	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst5

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint6

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz6

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma6 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma6	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst6

Bit	Name	Description	Access	Reset										
25:22	txfnum	Shared FIFO Operation-non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operation-these bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0										
21	stall	Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>STALL All Tokens not active</td> </tr> <tr> <td>0x1</td> <td>STALL All Tokens active</td> </tr> </tbody> </table>	Value	Description	0x0	STALL All Tokens not active	0x1	STALL All Tokens active	RO	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint7

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz7

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma7 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma7	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst7

10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint8

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz8

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma8 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma8	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst8

This register contains the free space information for the Device IN endpoint Tx FIFO.

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint9

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz9

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma9 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma9	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst9

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint10

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz10

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma10 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma10	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfsts10

15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint11

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz11

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma11 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma11	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

The frame in which data is received is updated in receive descriptor structure.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Endpoint Data PID not active</td> </tr> <tr> <td>0x1</td> <td>Endpoint Data PID active</td> </tr> </tbody> </table>	Value	Description	0x0	Endpoint Data PID not active	0x1	Endpoint Data PID active	RO	0x0
Value	Description									
0x0	Endpoint Data PID not active									
0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint12

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz12

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma12 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma12	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfst12

0x0	Endpoint Data PID not active									
0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint13

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz13

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma13 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma13	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	The core is transmitting NAK handshakes on this endpoint									
16	dpid	<p>Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Endpoint Data PID not active</td> </tr> <tr> <td>0x1</td> <td>Endpoint Data PID active</td> </tr> </tbody> </table>	Value	Description	0x0	Endpoint Data PID not active	0x1	Endpoint Data PID active	RO	0x0
Value	Description

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint14

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz14

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

diepdma14 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma14	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x0	The core is transmitting non-NAK handshakes based on the FIFO status									
0x1	The core is transmitting NAK handshakes on this endpoint									
16	dpid	<p>Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Endpoint Data PID not active</td> </tr> <tr> <td>0x1</td> <td>Endpoint Data PID active</td> </tr> </tbody> </table>	Value	Description	0x0	Endpoint Data PID not active	0x1	Endpoint Data PID active	RO	0x0
Value	Description									
0x0	Endpoint Data PID not active									
0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

diepint15

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

dieptsiz15

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepint0

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

doeptsiz0

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPEna/DOEPCTL0.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1 to 15. When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

doepdma0 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma0	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint1

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset						
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz1

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma1 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma1	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint2

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset						
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz2

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma2 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma2	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Bit	Name	Description	Access	Reset						
17	naksts	<p>When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>The core is transmitting non-NAK handshakes based on the FIFO status</td> </tr> <tr> <td>0x1</td> <td>The core is transmitting NAK handshakes on this endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	The core is transmitting non-NAK handshakes based on the FIFO status	0x1	The core is transmitting NAK handshakes on this endpoint	RO	0x0
Value	Description									
0x0	The core is transmitting non-NAK handshakes based on the FIFO status									
0x1	The core is transmitting NAK handshakes on this endpoint									
16	dpid	<p>Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Endpoint Data PID not active</td> </tr> <tr> <td>0x1</td> <td>Endpoint Data PID active</td> </tr> </tbody> </table>	Value	Description	0x0	Endpoint Data PID not active	0x1	Endpoint Data PID active	RO	0x0
Value	Description									
0x0	Endpoint Data PID not active									
0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint3

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz3

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma3 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma3	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Bit	Name	Description	Access	Reset						
17	naksts	<p>When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>The core is transmitting non-NAK handshakes based on the FIFO status</td> </tr> <tr> <td>0x1</td> <td>The core is transmitting NAK handshakes on this endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	The core is transmitting non-NAK handshakes based on the FIFO status	0x1	The core is transmitting NAK handshakes on this endpoint	RO	0x0
Value	Description									
0x0	The core is transmitting non-NAK handshakes based on the FIFO status									
0x1	The core is transmitting NAK handshakes on this endpoint									
16	dpid	<p>Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Endpoint Data PID not active</td> </tr> <tr> <td>0x1</td> <td>Endpoint Data PID active</td> </tr> </tbody> </table>	Value	Description	0x0	Endpoint Data PID not active	0x1	Endpoint Data PID active	RO	0x0
Value	Description									
0x0	Endpoint Data PID not active									
0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

Doepint4

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset						
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz4

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma4 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma4	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint5

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset						
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz5

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma5 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma5	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint6

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Bit	Name	Description	Access	Reset						
0	xfercompl	Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled This field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>No Interrupt</td> </tr> <tr> <td>0x1</td> <td>Transfer Completed Interrupt</td> </tr> </tbody> </table>	Value	Description	0x0	No Interrupt	0x1	Transfer Completed Interrupt	RO	0x0
Value	Description									
0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz6

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doepdma6 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma6	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

10:0	mps	<p>Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.</p>	RW	0x0						

doepint7

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

0x0	No Interrupt									
0x1	Transfer Completed Interrupt									

doeptsiz7

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

doeptsiz7 Fields

Bit	Name	Description	Access	Reset										
30:29	rxdpid	Applies to isochronous OUT endpoints only. This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>DATA0</td> </tr> <tr> <td>0x1</td> <td>DATA2 or 1 packet</td> </tr> <tr> <td>0x2</td> <td>DATA1 or 2 packets</td> </tr> <tr> <td>0x3</td> <td>MDATA or 3 packets</td> </tr> </tbody> </table>	Value	Description	0x0	DATA0	0x1	DATA2 or 1 packet	0x2	DATA1 or 2 packets	0x3	MDATA or 3 packets	RO	0x0
Value	Description													
0x0	DATA0													
0x1	DATA2 or 1 packet													
0x2	DATA1 or 2 packets													
0x3	MDATA or 3 packets													
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0										

Bit	Name	Description	Access	Reset
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0

doepdma7 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma7	Holds the start address of the external memory for storing or fetching endpoint data. for control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint8

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

30:29	rxdpid	<p>Applies to isochronous OUT endpoints only. This is the data PID received in the last packet for this endpoint. Use datax. Applies to control OUT Endpoints only. Use packetx. This field specifies the number of back-to-back SETUP data packets the endpoint can receive.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>DATA0</td> </tr> <tr> <td>0x1</td> <td>DATA2 or 1 packet</td> </tr> <tr> <td>0x2</td> <td>DATA1 or 2 packets</td> </tr> <tr> <td>0x3</td> <td>MDATA or 3 packets</td> </tr> </tbody> </table>	Value	Description	0x0	DATA0	0x1	DATA2 or 1 packet	0x2	DATA1 or 2 packets	0x3	MDATA or 3 packets	RO	0x0
Value	Description													
0x0	DATA0													
0x1	DATA2 or 1 packet													
0x2	DATA1 or 2 packets													
0x3	MDATA or 3 packets													
28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0										
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0										

doepdma8

DMA OUT Address.

doepdma8 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma8	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab8

DMA Buffer Address.

Bit	Name	Description	Access	Reset						
17	naksts	<p>When either the application or the core sets this bit: - The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. -for non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. -for isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>The core is transmitting non-NAK handshakes based on the FIFO status</td> </tr> <tr> <td>0x1</td> <td>The core is transmitting NAK handshakes on this endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	The core is transmitting non-NAK handshakes based on the FIFO status	0x1	The core is transmitting NAK handshakes on this endpoint	RO	0x0
Value	Description									
0x0	The core is transmitting non-NAK handshakes based on the FIFO status									
0x1	The core is transmitting NAK handshakes on this endpoint									
16	dpid	<p>Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0: DATA0 1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 0: Even (micro)frame 1: Odd (micro) frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Endpoint Data PID not active</td> </tr> <tr> <td>0x1</td> <td>Endpoint Data PID active</td> </tr> </tbody> </table>	Value	Description	0x0	Endpoint Data PID not active	0x1	Endpoint Data PID active	RO	0x0
Value	Description									
0x0	Endpoint Data PID not active									
0x1	Endpoint Data PID active									

Bit	Name	Description	Access	Reset						
15	usbactep	Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Not Active</td> </tr> <tr> <td>0x1</td> <td>USB Active Endpoint</td> </tr> </tbody> </table>	Value	Description	0x0	Not Active	0x1	USB Active Endpoint	RW	0x0
Value	Description									
0x0	Not Active									
0x1	USB Active Endpoint									
10:0	mps	Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0						

doepint9

This register indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

0x1	Transfer Completed Interrupt									

doeptsiz9

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLn.EPEna/DOEPCTLn.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

28:19	pktcnt	Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the RxFIFO.	RW	0x0										
18:0	xfersize	Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the RxFIFO.	RW	0x0										

doepdma9

DMA OUT Address.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C34
usb1	0xFFB40000	0xFFB40C34

Offset: 0xC34

Access: RW

doepdma9 RW 0x0															

doepdma9 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma9	Holds the start address of the external memory for storing or fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab9

DMA Buffer Address.

Module Instance	Base Address	Register Address
usb0	0xFFB00000	0xFFB00C3C
usb1	0xFFB40000	0xFFB40C3C

Offset: 0xC3C

Access: RO

doepdmab9 RO 0x0															

doepdmab9 Fields

Bit	Name	Description	Access	Reset
31:0	doepdmab9	Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. This register is present only in Scatter/Gather DMA mode.	RO	0x0

doepectl10

Out Endpoint 10.

Module Instance	Base Address	Register Address
